

# Legal Unbundling can be a Golden Mean between Vertical Integration and Separation

Felix Höffler<sup>1</sup> and Sebastian Kranz<sup>2</sup>

December 2007

## Abstract

We study an industry in which an upstream monopolist supplies an essential input at a regulated price to several downstream firms. Legal unbundling means that a downstream firm owns the upstream firm, but this upstream firm is legally independent and maximizes its own upstream profits. We allow for non-tariff discrimination by the upstream firm and show that under quite general conditions legal unbundling yields (weakly) higher quantities in the downstream market than vertical separation and integration. Therefore, typically, consumer surplus will be largest under legal unbundling. Outcomes under legal unbundling are still advantageous when we allow for discriminatory capacity investments, investments into marginal cost reduction and investments into network reliability. If access prices are unregulated, however, legal unbundling may be quite undesirable.

# 1 Introduction

In many industries vertically integrated firms are not only active in the final product market, but they also supply essential inputs to potential downstream competitors. Prominent examples are network industries, like energy, rail, or telecommunications where access to a transmission or a railway network is an essential input. Another example is the software industry where, e.g., Microsoft offers "compatibility" to Windows and at the same time competes in the applications market. An important and heavily researched policy question is: should vertical integration be allowed? Standard arguments in favor of integration are that integration at least partially overcomes the double marginalization problem and that it might provide better investment incentives for the upstream operations. The main motivation to vertically separate an integrated firm is that integration can lead to discriminatory behavior against downstream competitors.

We analyze a third alternative: legal unbundling. Legal unbundling means that the essential input must be controlled by a legally independent entity with an autonomous management, but a firm that is active in the downstream market is still allowed to own this entity. Ownership under legal unbundling entitles the downstream firm to receive the entity's profits, but interferences in the entity's operations are forbidden.

Forms of legal unbundling are commonly observed in network industries. Legal unbundling is the current standard requirement for the energy industry in Europe, and the related concept of "Independent System Operators" is also an option in the proposals for a new EU regulation.<sup>3</sup> In the US, forms of legal unbundling exist for natural gas pipelines and in large parts of the electricity transmission systems that are operated by Regional Transmission Organizations or Independent System Operators.<sup>4</sup> Similar forms of "partial separation" are also common in the telecommunications industry in Europe and the US.<sup>5</sup>

Irrespective of how the industry is vertically structured, the price for the essential input is usually regulated. Typically, regulators use linear tariffs above

---

<sup>3</sup>For the electricity market, see Directive 2003/54/EC, Articles 10 (1) and 15 (1), for the gas market, see Directive 2003/55/EC, Articles 9 (1) and 13 (1) and the proposal to amend this Directive issued 2007-09-19.

<sup>4</sup>See Federal Energy Regulatory Commission, Order 636 (issued 1992-04-18) for natural gas and Order 2000 (issued 1999-12-20) for electricity transmission.

<sup>5</sup>For the US see Section 272 of the Telecommunications Act of 1996; for the European Union see Directive 2002/21/EC, Article 13 (1b).

the marginal cost, e.g., in order to allow for the coverage of fixed costs. While non-discrimination with respect to the access tariff is relatively easy to impose,<sup>6</sup> non-tariff discrimination remains an important problem in practice. Regulators and competitors report of such "sabotage" in form of discriminatory information flows, undue delays in delivery of the service, overly complex contractual requirements, requiring unreasonably high bank guarantees and the like.<sup>7</sup> Our research question therefore is: How does legal unbundling compare to the outcomes of vertical integration and vertical separation if access prices are regulated while non-tariff discrimination cannot be prevented?

To answer this, we propose a fairly general setup. There is one upstream monopolist ( $F_0$ ), a potentially integrated affiliated downstream firm ( $F_1$ ), the "incumbent", and  $n - 1$  potential downstream competitors. The upstream firm produces an essential input at constant marginal cost  $c_0$ , which the downstream firms need in a fixed proportion to produce the final output. We impose no other restriction on the downstream firms' technologies, in particular, some or all competitors might be more or less efficient than the incumbent  $F_1$ . In the downstream market, the incumbent moves first; no other restrictions are imposed on the downstream competition. Strategies could, for example, affect quantities, (non-linear) prices, investments or entry decisions. That the incumbent moves first is mainly a simplifying assumption; we exemplify with Cournot competition that the main results also apply with simultaneous moves in the downstream market.

The upstream firm  $F_0$  sells the input to all downstream firms at a regulated linear access price  $a$  above marginal costs (we also extend this setup to more general forms of price regulation). Although price discrimination is not possible,

---

<sup>6</sup>Although this also can be an issue, e.g., if non-linear tariffs are used. They might be tailored such that only the subsidiary of the integrated company can realize low prices. Exactly for this reason, regulators are skeptical about such tariffs. See, e.g., European Commission, Energy Sector Inquiry, Competition report on energy sector inquiry (Jan. 10, 2007), part 1, para 155, p. 58. One example was the access to the Deutsche Telekom network required to offer narrowband internet access (a product called T-Online-Connect-Interconnect), where Deutsche Telekom offered quantity rebates which were only realized by its own subsidiary "T-Online". The regulatory authority ruled this to be discriminatory. See the German regulator's annual report "Tätigkeitsbericht 1998/99", p. 67.

<sup>7</sup>See, e.g., European Commission, Energy Sector Inquiry (Jan. 10, 2007), Competition report on energy sector inquiry, part 1, para 169, or para 493, p. 163: For the Telecommunications sector, see for instance a submission of the VATM (Association of competitors to Deutsche Telekom) to the European Commission, "Markteintrittsbarrieren im deutschen Telekommunikationsmarkt", September 2001.

$F_0$  can "sabotage" the downstream firms, i.e., it can influence the cost and demand situation of each downstream firm.

Four different vertical structures are compared: integration of  $F_0$  and  $F_1$ ; separation (i.e., all firms are independent); legal unbundling ( $F_0$  is legally independent and maximizes its own profits but is owned by  $F_1$ ); additionally, we discuss also "reverse unbundling" where the downstream firm is legally unbundled — although this seems to be of less relevance in practice.

Our main result is that legal unbundling leads to (weakly) higher levels of output than all the other vertical structures. In many cases, higher output will translate into (weakly) higher consumer surplus under legal unbundling. The intuition why legal unbundling leads to higher quantities than vertical integration is as follows. Due to the access price regulation, upstream profits of  $F_0$  are maximized when total output is maximal. Thus, if  $F_0$  is legally unbundled, it wants to maximize total output and refrains from sabotage of the downstream firms. In contrast, with vertical integration,  $F_0$  also takes into account downstream profits of  $F_1$  and may engage in sabotage of downstream competitors in order to increase downstream profits. We call this the "*sabotage effect*".

When comparing legal unbundling to vertical separation, more complex forces are at work. First, since in both cases the upstream firm wants to maximize total output, neither under legal unbundling nor under vertical separation will the upstream (usually) sabotage downstream firms, i.e., there is essentially no sabotage effect.

Second, while a vertically separated downstream firm  $F_1$  is interested only in its own profits, under legal unbundling  $F_1$  also has an interest in high upstream profits — and thereby in a high overall output. Under legal unbundling, the downstream firm  $F_1$  will therefore select strategies that yield higher total output compared to separation. We call this the "*downstream expansion effect*".

Part of the downstream expansion effect is explained by the well-known intuition from the double marginalization problem: Under legal unbundling the incumbent calculates with the true input costs  $c_0$  and not — as under separation — with the higher access price  $a$  and is therefore willing to expand output. In addition, the incumbent takes into account that he can induce an output change by downstream competitors. We call this the "*induced output effect*". For instance, in the case of legal unbundling and price competition, the incumbent sets a lower price than under separation, in order to increase the output of entrants, who respond to the more aggressive pricing by lowering their own prices. That the

induced output effect is indeed additional to the effect from double marginalization becomes apparent when one considers more sophisticated regulatory schemes that solve the double marginalization problem. Even under those schemes, the induced output effect can lead to output expansion under legal unbundling, as discussed in Section 5.1.

Since one of the main policy concerns is about efficient network investments, we extend our analysis to different forms of investment decisions. Given our quantity results, it is quite intuitive that incentives for reducing the upstream firm's marginal costs are highest under legal unbundling. We also discuss capacity investments, which can discriminate between downstream firms, and incentives to invest in network reliability. For these two types of investments it is not generally clear that legal unbundling provides the highest investment incentives, although legal unbundling exhibits some desirable properties also for these sorts of investment decisions.

Despite its great policy relevance in the European Union, there is little literature on legal unbundling. One important exception is Cremer, Crémer, and De Donder (2006). They conceptually introduced the idea to model legal unbundling in the form that the unbundled firm independently maximizes its own profits while being a fully-owned subsidiary. Their approach differs from ours since they assume that the downstream firm is legally unbundled (this is our case of "reverse" unbundling). We focus on the situation where the upstream firm is legally unbundled, which seems to be closer to legal practice where the network operations have to be legally independent. Further differences are that they focus on relation-specific investments but do not consider sabotage; furthermore, in their setup access prices are not set by the regulator, and downstream firms always act as price takers.

In a companion paper, Höffler and Kranz (2007), we analyze the effects of imperfections in legal unbundling. This provides a robustness check for our results and is briefly reviewed in Section 6.

Apart from this, our paper is related to different strands of literature, namely, in general, to the literature on vertical integration, where an overview is provided, e.g., in Perry (1989). Vickers (1995) is also related, who compares vertical integration with separation under access price regulation and finds mixed welfare results. More recent papers compare investment incentives under vertical integration and separation, like Buehler, Schmutzler, and Benz (2004), who find that generally incentives for quality investments are higher under vertical integration.

Our paper is also related to a literature that focuses on the issue of sabo-

tage; see, e.g., Economides (1998), Beard, Kaserman, and Mayo (2001) or, for an overview, Mandy (2000). Most recently, Mandy and Sappington (2007) compared cost increasing to quality decreasing sabotage in vertical relationships. We analyze a more general setup without restrictions on the downstream firms' cost functions, the strategic variables of downstream competition or the impact of sabotage. We also allow for more general regulatory schemes than linear access pricing and introduce legal unbundling as an alternative ownership structure.

Studying legal unbundling also offers interesting insights into the role of ownership in the theory of the firm. The defining characteristic of ownership can be the right for residual cash-flows (i.e. profits) as in Alchian and Demsetz (1972) or, alternatively, a residual right of control as in Grossman and Hart (1986). Whereas under vertical integration both rights are granted to the incumbent, under legal unbundling ownership entitles to claim residual cash-flows, but grants no (or very limited) residual rights of control.

The remainder of the paper is organized as follows. Section 2 presents the basic model, where we assume a regulated linear access price, and where we derive the basic results. Section 3 examines the different types of upstream investments. Several results are illustrated for the case of price competition with homogenous goods in Section 4, which also includes a complete welfare analysis for this example. In Section 5, we present a general class of regulatory pricing schemes (including two-part tariffs for downstream firms), for which our results hold. Section 6 discusses the results, policy implications, and the effects of imperfect legal unbundling. Section 7 concludes. Unless otherwise stated, all proofs can be found in the appendix.

## 2 Basic model and results

### 2.1 Assumptions and main results

**Structure and Regulation** There is a monopolistic upstream firm  $F_0$  that produces a good at constant marginal costs  $c_0$ , which is used as input good for  $n$  competing downstream firms,  $F_1, \dots, F_n$ . Each downstream firm needs a constant and identical amount of the input good to create an output good. For simplicity, we normalize input quantities such that each firm needs exactly one unit of the input good to create one unit of an output good.

**Non-tariff Discrimination** We assume  $F_0$  is a regulated natural monopoly,

e.g. the owner of an essential transmission network in electricity or telecommunication markets. The regulator fixes a per-unit access price  $a > c_0$  that  $F_0$  must charge from all downstream firms (in Section 5, more general pricing schemes are considered). The regulator can enforce the access price but cannot prevent  $F_0$  from hindering some or all downstream firms in some other way.  $F_0$  chooses an action  $h \in H$  that specifies some sabotage strategy against downstream firms, like non-disclosure of essential information or undue delays in the provision of ancillary services. Sabotage can increase access costs for certain downstream firms or reduce their demand by creating inconveniences for customers. We assume that the choice of  $h$  has no direct impact on the profit of  $F_0$ , although perhaps indirectly it does, if it changes the total quantity sold.

**Timing** First,  $F_0$  chooses its sabotage strategy  $h$ . In the extensions of Section 3,  $F_0$  also makes investment decisions. Then, downstream firms engage in downstream competition. An action of downstream firm  $i$  is denoted by  $x_i$  and  $x = (x_1, \dots, x_n)$  denotes a profile of actions selected by the downstream firms. Downstream actions can describe a broad range of decisions, for example about quantities, prices, investments, entry or sabotage against competitors.

Unless otherwise stated, we assume that the downstream incumbent  $F_1$  moves first and that  $F_2, \dots, F_n$  can observe the chosen action  $x_1$ . Whether the other downstream firms afterwards move simultaneously or sequentially does not matter for our results. The assumption that the incumbent moves first significantly facilitates the analysis. The basic intuition carries over also to simultaneous move games; however, for these games some additional standard regularity assumptions are required, as we exemplify for Cournot competition.

We are focusing on subgame perfect equilibria in each of the different games.

**Downstream Market and Payoffs** Downstream actions, together with sabotage, determine downstream firm  $i$ 's output  $q_i(x, h)$ , its market price  $p_i(x, h)$  and total costs  $C_i(x, h|a)$ . Total output quantity is given by  $Q(h, x) = \sum_{i=1}^n q_i(x, h)$ .<sup>8</sup>  $F_0$ 's profits are given by

$$\pi_0(x, h|a) = (a - c_0)Q(x, h) - K + S \quad (1)$$

The constant  $K$  represents fixed costs and the constant  $S$  possible state subsidies. Note that these upstream profits  $\pi_0$  are strictly increasing in total output  $Q$ .

---

<sup>8</sup>If firms play mixed strategies, these variables denote expected values. In that case, we assume that all firms are risk-neutral.

Profits of downstream firm  $i$  are given by

$$\pi_i(x, h|a) = p_i(x, h)q_i(x, h) - C_i(x, h|a) \text{ for } i = 1, \dots, n \quad (2)$$

Besides a regularity condition that subgame-perfect equilibria exist in every continuation game (Condition C1 below), we make no restrictions on functional forms.

**Vertical structures** We compare the following four vertical structures.

$v$  : Vertical integration.  $F_0$  and  $F_1$  maximize their joint profits  $\pi_{01}$ , given by

$$\pi_{01} = \pi_1 + \pi_0 \quad (3)$$

$s$  : Vertical separation. All firms maximize their own profits  $\pi_i$ .

$u$  : Legal unbundling:  $F_0$  maximizes its own profits, whereas  $F_1$  maximizes the joint profits  $\pi_{01}$ .

$r$  : Reverse legal unbundling: For comparison reasons we also consider this case where  $F_0$  maximizes joint profits  $\pi_{01}$  and  $F_1$  maximizes its own profits  $\pi_1$ .

The entering downstream firms  $i = 2, \dots, n$  maximize their own profits  $\pi_i$  under all vertical structures.

Legal unbundling requires that the network part, or more generally, the part of the company controlling the essential facility, has to be separated into a legally independent entity. The EU legislation explicitly states, however, that legal unbundling does not imply that the integrated firm has to sell the network operations. Thus, 100% ownership of the network operations  $F_0$  by the incumbent  $F_1$  is current practice under legal unbundling in many European countries (e.g. in the energy industries in France and Germany).

Legal unbundling in our model is perfect in the sense that we assume that regulators are able to incentivize the management of  $F_0$  such that it maximizes only upstream profits  $\pi_0$  without considering the incumbent's downstream profits  $\pi_1$ . Arguably, this does not always mirror the actual practice of legal unbundling; however, existing legislation explicitly excludes direct instructions of the mother company (Directive 2003/54/EC, Article 10 and 15) or prescribes arm's-length relations (US Telecommunications Act 1996, Section 272 (b) [5]). A couple of other rules and initiatives may help to implement legal unbundling in a way that comes closer to the "ideal" form assumed in the model. This includes the current requirement in the EU energy industry to have strict personnel separation, ensuring that professional interests of the upstream firm's employees are separated from downstream interests (e.g. the network unit's managers should not participate in the group's stock option programs). Furthermore, strict compliance with these

independence requirements are compulsory for 'Independent System Operators' in the new EU proposal for an amendment of Directive 2003/54/EC (issued 2007-09-19). However, to see how our results are affected by a less stringent separation of interests, we discuss the effects of "imperfect legal unbundling" in Section 6.

**Access prices** When we compare the different vertical structures, we consider a given access price  $a$  that is the same in every vertical structure. We will perform this comparison for every possible access price  $a > c_0$ . As we will discuss below, our results are more general than if we had compared only the optimum access price for each vertical structure.

**Regularity conditions** Since we compare different vertical structures, we essentially compare outcomes of different games. Note, however, that — although payoffs of  $F_0$  and  $F_1$  differ — the timing, the set of players and the strategy space is the same under every vertical structure. To facilitate the comparison of different vertical structures, we introduce two regularity conditions. A *situation* shall describe a vertical structure and a non-terminal history of the multi-stage game, i.e. a history where at least one player still has to move. In order to avoid technical complications that could arise if some continuation games have no subgame-perfect equilibrium, we require:

**C1** *In every situation there is a subgame-perfect continuation equilibrium.*

Note that for some forms of downstream competition and sabotage technologies, a given situation can have multiple subgame-perfect continuation equilibria. To simplify comparison between vertical structures in those cases, we also make a regularity condition on equilibrium selection:

**C2** *Assume two situations have an identical set of subgame-perfect continuation equilibria. Then in both situations the same subgame-perfect continuation equilibrium shall be selected from this identical set.<sup>9</sup>*

This regularity condition avoids tedious comparison of sets of equilibria. Note that C2 is obviously not needed when, in every situation, there is a unique continuation equilibrium. The following remark summarizes the essential implications of the regularity conditions for the subgame-perfect equilibria in our model:

**Remark** *Since downstream entrants' profits do depend on  $h$  and  $x$ , but not directly on the vertical structure, our regularity condition implies that the equilibrium actions of downstream entrants are a function of  $h$  and  $x_1$  only. Furthermore, as-*

---

<sup>9</sup>Note that there is no conceptual problem in determining whether continuation equilibria under different vertical structures are identical or not, since equilibria are strategy profiles and the strategy space is the same under every vertical structure.

suming the same sabotage strategy  $h$  is chosen under legal unbundling and vertical integration, then downstream firms choose the same equilibrium actions  $x$ , since the incumbent maximizes joint profits  $\pi_0 + \pi_1$  under both vertical structures.

We are now ready to state our first basic result.

**Proposition 1** *Under legal unbundling, total output  $Q$  and upstream profits  $\pi_0$  are (weakly) higher than under vertical integration. The result still holds under downstream competition in simultaneous moves.*

Intuitively, total output is higher under legal unbundling than under vertical integration, because vertical integration can cause a *sabotage effect*. Recall from the remark that the outcome under legal unbundling and vertical integration can differ only if  $F_0$ 's sabotage strategy  $h$  differs. (This still holds true if the downstream incumbent moves simultaneously with downstream entrants.) Under legal unbundling,  $F_0$  considers only upstream profits  $\pi_0$  and therefore chooses  $h$  in order to maximize total output  $Q$ . This choice can usually be interpreted as performing no sabotage. Under vertical integration, however,  $F_0$  has incentives to sabotage downstream competitors whenever sabotage sufficiently increases the incumbent's downstream profits  $\pi_1$  — even though the sabotage may decrease upstream profits  $\pi_0$  and total output  $Q$ . We now state our second basic result:

**Proposition 2** *Under legal unbundling total output  $Q$  and upstream profits  $\pi_0$  are (weakly) higher than under separation.*

The intuition for Proposition 2 differs from that of Proposition 1. Under both legal unbundling and separation, the upstream firm  $F_0$  wants to maximize total output  $Q$ , i.e. there is no sabotage effect. In contrast to separation, under legal unbundling the downstream incumbent  $F_1$  participates in the upstream profits  $\pi_0$  and therefore has an interest to select a decision  $x_1$  that expands total output  $Q$ . We call this the *downstream expansion effect*.

To gain further intuition for the downstream expansion effect, we consider some specific examples of downstream competition. It is helpful to decompose the output expansion under legal unbundling into two parts: the change in the incumbent's own output  $q_1$  and an *induced output effect* that measures the aggregate change in downstream entrants' output.

Consider first the simple case that there are no entrants and  $F_1$  is a downstream monopolist, i.e. there is no induced output effect. Then the output expansion under legal unbundling is due to the intuition known from the double marginalization

problem: Under legal unbundling  $F_1$  considers only the true marginal costs  $c_0$  instead of the higher access price  $a$  and therefore chooses a higher output than under separation.

In the presence of entrants, the incumbent additionally takes the induced output effect into account. In Section 4, we discuss in detail an example where firms compete in prices. Basically, the incumbent sets an aggressively low price in order to induce higher output by the downstream entrants who match the low price. Even if the access price  $a$  converges to the marginal cost  $c_0$ , the quantity under legal unbundling is still larger than under vertical separation since—although the double marginalization problem vanishes—the induced output effect is still present.

If firms compete in quantities, a quantity expansion by the incumbent typically induces an output reduction by the entrants. Since the incumbent moves first, he will always take the induced output effect into account and we will thus never find that  $F_1$  takes an action such that total output is lower under legal unbundling than under separation. This means the downstream expansion effect will never be negative when  $F_1$  moves first.

## 2.2 Additional results

**Legal unbundling vs separation under simultaneous moves** If the incumbent and entrants move simultaneously,  $F_1$  still prefers higher total output under legal unbundling than under separation. We cannot, however, in general exclude that the incumbent’s desire to have higher total output may paradoxically lead to lower total output in equilibrium. Thus, the result of Proposition 2 will typically hold only under additional assumptions when downstream firms move simultaneously. An example for this is to consider Cournot competition downstream and to assume a specific sabotage technology: Assume that sabotage linearly increases costs, i.e.  $h = \{h_1, \dots, h_n\} \in R^n$  such that the costs of firm  $i$  become  $C_i(h) = (a + h_i) q_i + \tilde{C}_i(q_i)$  where  $\tilde{C}_i(q_i)$  is just some arbitrary function of  $q_i$ . With this assumption, we retain our result of larger quantities under legal unbundling also for the case of simultaneous quantity competition:

**Proposition 3** *Consider the special case of the linear sabotage technology. Assume downstream firms compete by simultaneously setting quantities (goods can be differentiated). Then total output is (weakly) higher under legal unbundling than under both separation and vertical integration.*

Under Cournot competition the incumbent does not directly take the induced output effect into account, i.e. its best reply function takes competitors' output as given. The downstream expansion effect is therefore driven by the double marginalization problem: Under legal unbundling, the incumbent calculates with true marginal costs  $c_0$  instead of the higher access price  $a$ . Typically, a reduction in one firm's marginal costs will lead to a higher total output in the Cournot equilibrium (see, for example, Farrell and Shapiro (1990) for weak regularity conditions for the case of homogeneous goods). The reason that Proposition 3 also holds for cases where total output is increasing in a firm's marginal cost, is that the upstream firm can then prevent output reduction by increasing the incumbent's marginal costs via the linear sabotage technology.

Let us finally discuss simultaneous price competition with differentiated products in the downstream market. Under price competition, the incumbent wants to set lower prices under legal unbundling than under separation, because lower prices increase output. As long as prices are strategic complements, i.e. entrants react to a lower price of the incumbent by lowering their own prices, and total output is weakly decreasing in each firm's price, we find that under legal unbundling no firm sets higher prices and total output is weakly higher than under separation.

**Implications of the output results** Our output results suggest that from the consumers' perspective, legal unbundling is likely to be superior to the other two vertical structures. In particular, if the downstream products are homogenous (like, e.g., voice calls, electricity, or gas) and if downstream firms charge linear tariffs, it is immediate that higher quantities yield also a higher consumer surplus.

**Corollary 1** *If output goods are perfect substitutes and downstream firms use linear tariffs, consumer surplus is weakly highest under legal unbundling.*

Legal unbundling can also be preferred by taxpayers, since  $F_0$  makes higher profits than under the other vertical structures: if the regulatory regime requires an ex ante subsidy that ensures that  $F_0$  will break even, then such a subsidy would be lowest under legal unbundling.

**Corollary 2** *The minimal state subsidy, which guarantees that  $F_0$  makes no losses, is lowest under legal unbundling.*

**Total welfare** Without assumptions on how discrimination works and how downstream competition works, results on total welfare are not possible. Clearly

there are cases where legal unbundling leads to higher output but to lower welfare, for example if there are sunk costs and legal unbundling facilitates excess entry (see the seminal paper by Mankiw and Whinston (1986)). Nevertheless there will be many cases where total welfare is also highest under legal unbundling. One such case — a homogeneous goods duopoly with price competition — is exemplified in Section 4.

**Comparison under optimal access prices** Assume consumer surplus (and / or total welfare) is increasing in total output and regulators consider an access price to be optimal if it maximizes total output under the restriction that the upstream firm can recover its fixed costs. In general, the optimal access price can depend on the vertical structure, and one may be interested to compare the total output, under the condition that under each vertical structure the optimal access price is selected. Our results imply that legal unbundling leads to (weakly) higher total output than separation and vertical integration also for the case that such optimal access prices are chosen in every vertical structure. Recall that we have shown that for every access price  $a > c_0$  legal unbundling leads to (weakly) higher output than the other vertical structures. Thus even for the access prices that yield the highest output under separation or vertical integration, legal unbundling will lead to (weakly) higher output and (weakly) higher upstream profits. The output difference will even increase if for legal unbundling one would also choose the optimal access price.

**Reverse legal unbundling** In order to make our results comparable to Cremer, Crémer, and De Donder (2006), what is left to discuss is the case of "reverse unbundling". Recall that reverse legal unbundling means  $F_0$  maximizes  $\pi_0 + \pi_1$ , whereas  $F_1$  has an independent management and maximizes  $\pi_1$ . In practice, this would imply that e.g. a integrated electricity company would have to form a legally independent sales unit which is owned by the network operations (or by the whole group, including generation facilities). The important point is that with reverse legal unbundling the essential facility would not be separated into an independent unit. We find that reverse unbundling leads to lower quantities in equilibrium compared to vertical separation and, by Proposition 1, also to lower quantities than legal unbundling.

**Proposition 4** *Total output  $Q$  and upstream profits  $\pi_0$  under reverse legal unbundling are weakly lower than under separation.*

This finding is different to the results of Cremer, Crémer, and De Donder (2006), because they compare reverse legal unbundling with separation in a model that focuses on relation-specific investments; in this framework, reverse legal unbundling is better suited than separation to overcome the hold-up problem.

## 3 Investments

### 3.1 Capacity Investments and Discriminatory Investments

Many types of upstream investments will influence output by downstream firms, e.g. by changing the network capacity. Benefits and impediments from such investments can accrue differently to different downstream firms. For example, investments into interconnection capacity to a foreign country benefit foreign energy producers who want to sell in the domestic market of the network operator.

In the policy debate, there are severe concerns that vertical integration and legal unbundling lead to socially inefficient allocations of such investments, because of overlapping interests of the network operator and the downstream incumbent. The EU Commission states:

Vertically integrated network operators have no incentive for developing the network in the overall interests of the market and hence for facilitating new entry at generation or supply levels; on the contrary, they have an inherent interest to limit new investment when this will benefit its competitors and bring new competition onto the incumbent's "home market". Instead, the investment decisions made by vertically integrated companies tend to be biased to the needs of supply affiliates. Such companies seem particularly disinclined to increase interconnection or gas import capacity and thereby boosting competition in the incumbent's home market to the detriment of the internal market.<sup>10</sup>

The Commission also makes clear that in its opinion only ownership unbundling, i.e. complete separation, can effectively solve this problem:

Economic evidence shows that ownership unbundling is the most effective means to ensure choice for energy users and encourage invest-

---

<sup>10</sup>Proposal for amending Directive 2003/54/EC concerning common rules for the internal market in electricity, (issued 2007-09-19), p.5.

ment. This is because separate network companies are not influenced by overlapping supply/generation interests as regards investment decisions.<sup>11</sup>

As we have shown in our basic model, not all overlapping interests are problematic. Under legal unbundling, the downstream expansion effect as one sort of an overlapping interest, is rather beneficial. Therefore, a more careful analysis of the investment incentives may turn out to be useful.

For the theoretical analysis it is helpful to split  $F_0$ 's investment decisions into two steps. One step is to decide on the allocation of investment if the total amount that shall be invested is given. The other step is to decide which total amount shall be invested.

**Investment allocation with given budget** We first analyze  $F_0$ 's allocation decision, assuming that the total amount of investment spending is given. We simply take our basic model and interpret  $F_0$ 's strategic variable  $h$  not only as a sabotage strategy, but also as a decision about the investment allocation, which influences downstream firms' costs and output. This interpretation is completely consistent with our model where downstream firms' output, prices and costs are given by some general functions  $q_i(x, h)$ ,  $p_i(x, h)$  and  $C_i(x, h|a)$ . It is also fulfilled that the allocation of investment has no influence on  $F_0$ 's costs, because the total amount invested is assumed to be given in this step.

Thus, our output results also apply, i.e., for a given sum of investment,  $F_0$  will under legal unbundling always choose that allocation of investment that maximizes total output.

**Endogenous investment budget** Examining the second step, we cannot rule out, however, that the total amount of investment is lower under legal unbundling than under the alternative vertical structures. There even exist cases, where the resulting quantities can be lower under legal unbundling.

We first illustrate why investments  $I^s$  and resulting total output  $Q^s$  under separation may exceed the investments  $I^u$  and total output  $Q^u$  under legal unbundling in some circumstances. Assume that (i) the incumbent is more efficient than the entrants, such that absent an investment, no entrants would be active and (ii) an investment would yield a level playing field for entrants and the incumbent. Under separation and without investment, the double marginalization problem would

---

<sup>11</sup>EU Commission, An Energy Policy for Europe, p. 7, Brussels, 10.1.2007, COM(2007) 1 final.

lead to a quantity lower than under legal unbundling. Thus, investing would yield a large increase in downstream quantities if, due to the investment, we moved from, say, a downstream monopoly to a Bertrand duopoly with identical costs. This increases upstream profits significantly and implies that the investment would be undertaken even if it is relatively costly. With legal unbundling, however, the network unit  $F_0$  might find it optimal not to invest, since it can anticipate that in the quantity decision of the incumbent  $F_1$ , the double marginalization problem is internalized and the quantity is relatively large already without an investment.

That investments under vertical integration,  $I^v$ , can be higher than under legal unbundling,  $I^u < I^v$ , is less surprising and applies already in quite intuitive examples. Consider an investment that benefits only the incumbent  $F_1$ , who might then be able to drive competitors out of the market. This might reduce overall quantity, such that with legal unbundling the network unit  $F_0$  would abstain from such an investment. While, in this case, investments are lower under legal unbundling, quantities will (typically) be higher under legal unbundling. However, it is not possible to generally rule out that legal unbundling with discriminatory investments can yield lower quantities than vertical integration.

Although total output may be lower under legal unbundling when the investment budget is endogenous, we can establish the following results:

**Proposition 5** *With capacity investments  $F_0$ 's profits from network operations  $\pi_0$  minus investment costs are weakly higher under legal unbundling than under both separation and vertical integration. Total output fulfills the following inequalities:*

$$(a - c_0)(Q^s - Q^u) \leq I^s - I^u \text{ and } (a - c_0)(Q^v - Q^u) \leq I^v - I^u.$$

Concerns for the incumbent's downstream profits play no role in those cases where investment levels are lower under legal unbundling. If investments and total output are lower under legal unbundling this is because higher investment is not worthwhile for the network operator itself.

The inequalities of Proposition 5 show that the output differences  $Q^s - Q^u$  and  $Q^v - Q^u$  can become large only if the difference in investment costs becomes large. One can, therefore, conjecture that such "expensive" expansions of downstream quantities are not welfare-enhancing. However, a comprehensive welfare analysis is not possible in our general framework.

The inequality also shows that possible under-investment may be reduced by increasing the access price  $a$ . This might be done in ways that do not distort down-

stream firms' demand when using the more general regulatory schemes illustrated in Section 5.

### 3.2 Investments in reducing upstream marginal costs

We now consider process innovations, i.e., investments of  $F_0$  which reduce its marginal costs  $c_0$  by some amount  $\delta$ . Investment costs  $I(\delta)$  are strictly increasing in the level of marginal costs reduction  $\delta$ . We first establish the following helpful lemma, which just proves the intuitive idea that for a lower level of upstream marginal costs total output will be weakly higher.

**Lemma 1** *Total output under legal unbundling is weakly decreasing in  $F_0$ 's marginal cost  $c_0$ .*

Provided with this intuitive result, we can show that investments and resulting output are highest with legal unbundling.

**Proposition 6** *Investment into marginal cost reduction and total output under legal unbundling are weakly higher than under vertical separation and vertical integration.*

This investment result is, of course, mainly driven by the output results of Propositions 1 and 2. When a higher quantity is sold under legal unbundling there are obviously higher gains from cost reduction. Although intuitive, Proposition 6 is not completely trivial, since investments change the output and the extent to which marginal cost reduction increases output can be larger under vertical integration than under legal unbundling. Proposition 6 shows that investments are nevertheless always weakly higher under legal unbundling.

### 3.3 Investments into network safety and reliability

An important issue for energy and railway networks is safety and reliability. If the network breaks down, severe costs may be inflicted upon the network operator itself, on downstream firms, as well as on final consumers and other on members of society.

Appropriate investments into network reliability are therefore an important issue. Integrated electricity companies sometimes claim that vertical integration is essential to guarantee reliable network operations. One may argue that reliability

investments could, indeed, be larger under vertical integration, since not only losses of the network operator but also losses of the own downstream operations are taken into account. However, as long as the losses for the rest of society are not considered, reliability investments will be too low under all vertical structures, including vertical integration.

Sufficient levels of reliability investments therefore require contractual solutions that can impose fines in case of network break-downs or — in cases where contractual solutions are not feasible — fines imposed by the regulator or direct regulation. We do not see a compelling reason why such contractual and regulatory arrangements should be more difficult to achieve under legal unbundling than under the other vertical structures.

Sometimes, however, there may be problems to identify who was responsible for some network failure. Was it a mistake on the part of the upstream firm or on the part of the downstream firm that led to the break-down? In those cases there may be welfare losses due to costly litigation. When  $F_0$  and  $F_1$  are vertically integrated there may be some advantage, because for outsiders it is not important whether the upstream or downstream operations of the integrated firm were responsible for some failure. But also under legal unbundling there should be less costly litigation between  $F_0$  and  $F_1$ , since  $F_1$  receives all profits from  $F_0$  and has therefore no interests in a costly law suit.

## 4 Example: Duopolistic Price Competition

In the following, we illustrate the output result for a downstream duopoly that sells a homogeneous product, like electricity, and competes in prices (with  $F_1$  moving first). This example provides two additional insights. First, it allows for a full welfare analysis, showing that indeed legal unbundling yields the highest level of social surplus. Second, it illustrates that the downstream expansion effect is not exclusively driven by the double marginalization problem. We will make precise that the downstream expansion effect is "significant" even when the double marginalization problem becomes arbitrarily small.

**Assumptions** There are two downstream firms selling perfect substitutes. Total demand is given by a downward sloping demand function  $Q(p)$ ,  $Q'(p) < 0$ . We maintain the assumption that the incumbent  $F_1$  moves first. We assume constant marginal cost of the downstream firms, with a cost disadvantage for the incumbent. Sabotage linearly increases downstream costs. Thus, cost functions

are given by

$$C_i(q_i) = (c_i + a + h_i) q_i \text{ for } i = 1, 2$$

with  $c_1 > c_2$ . Considering a cost disadvantage for the incumbent is of interest since a standard argument for liberalizing markets is to allow more efficient firms to enter the downstream market.

To avoid uninteresting case distinctions, we make some regularity conditions. First, we assume that for some prices above the incumbent's marginal cost plus access price  $a + c_1$  there is still positive demand, i.e. a separated incumbent could make positive profits if it were a downstream monopolist. Second, we assume that if  $F_2$  were a monopolist on the downstream market, its optimal monopoly price lies above  $a + c_1$ . Third, we assume that the access price  $a$  is not so high that it is Pareto-dominated by some lower access price. This means it is not the case that all firms and consumers would be weakly better off (and at least one of them strictly better off) by some lower access price.

As is well known, in this set-up multiple equilibria can arise. We only consider equilibria in which firms do not play weakly dominated strategies.

Finally, for the question of how the market is split between the two firms in case they choose identical prices, we make the following tie-breaking assumptions. If the price is above  $F_2$ 's marginal costs, i.e.  $p > c_2 + a$ , we assume that  $F_2$  gets the whole market (for the out-of-equilibrium event that  $p_1 = p_2 < c_2 + a$ , we assume  $F_1$  gets the whole market). This captures the idea that if prices were discrete on a sufficiently fine grid then  $F_2$  as second mover would prefer minimally to undercut the price if  $p > c_2 + a$  and prefer not to sell any output if  $p < c_2 + a$ .

If the price is equal to  $F_2$ 's marginal cost, i.e.  $p = c_2 + a$ , then  $F_1$  can decide whether  $F_1$  gets the whole market,  $F_2$  gets the whole market, or the market is split equally, i.e.  $q_1 = q_2 = \frac{1}{2}Q$ . This captures the idea that if prices were discrete,  $F_1$  could either set a price slightly above  $F_2$ 's marginal cost, in which case  $F_2$  gets the whole market, exactly split the market at  $F_2$ 's marginal cost, or slightly undercut  $F_2$ 's marginal cost to get the whole market.

**Vertical separation** This is the typical Bertrand case, except for the fact that  $F_1$  moves first. We find the following result:

**Lemma 2** *Under separation in every equilibrium  $F_2$  gets the whole market. The infimum of the market prices from all equilibria where no firm plays a weakly dominated strategy is given  $p = a + c_1$ .*

The price  $p = a + c_1$ , which equals the high cost firm's marginal cost, is the

typical Bertrand outcome. Nevertheless there are additional equilibria. As under simultaneous moves, there are equilibria with prices between  $a + c_2$  and  $a + c_1$ , but those are equilibria where  $F_1$  plays a weakly dominated strategy. If there is only a small doubt that  $F_2$  will not undercut  $F_1$ , then  $F_1$  will never set a price below its own marginal cost  $a + c_1$ . Since  $F_1$  moves first and always makes zero profits, there are also equilibria with prices above  $a + c_1$ , i.e. a price of  $a + c_1$  is not the only outcome but the welfare optimal outcome when we neglect weakly dominated strategies.<sup>12</sup>

**Legal unbundling** Under legal unbundling  $F_0$  again wants to maximize total output and therefore will not sabotage. Contrary to vertical separation, now the downstream incumbent  $F_1$  has an incentive to increase total output, since  $F_0$ 's profits will accrue to  $F_1$  under legal unbundling. Therefore  $F_1$  will price more aggressively in order to increase output and thereby upstream profits sufficiently. This form of aggressive pricing is taken to the extreme in our case of price competition with homogeneous goods, because here  $F_1$  prices more aggressively without even having some positive market share:

**Lemma 3** *Under legal unbundling  $F_0$  sets  $h_2 = 0$ .  $F_1$  and  $F_2$  both set prices  $c_2 + a$  and  $F_2$  gets the whole market.*

Note that even though the price set by  $F_1$ ,  $p_1 = a + c_2$ , can be below  $F_1$ 's true marginal costs  $c_0 + c_1$ , it is not a weakly dominated strategy for  $F_1$  to set such a price — in contrast to what we found under vertical separation. This is because if  $F_1$  would set a higher price,  $F_2$  would react with a higher price and total output, and therefore the profit of the integrated firm  $\pi_0 + \pi_1$  would be reduced.

**Vertical integration** With vertical integration, there are two candidates for an equilibrium. Either the upstream firm uses sabotage in order to drive  $F_2$  out of the market (the "monopolistic" outcome), or  $F_0$  does not sabotage  $F_2$  and then  $F_1$  acts in the same way as under legal unbundling (the "competitive" outcome).

**Lemma 4** *If  $F_0$  and  $F_1$  are integrated. There are two candidates for equilibrium: (m) monopoly case: Set  $h_2 = \infty$  and let  $F_1$  serve the whole market at the monopoly price of the integrated firm, denoted by  $p_{01}^m$ .*

---

<sup>12</sup>To be precise, in the equilibrium with a price of exactly  $a + c_1$ ,  $F_1$  also plays a weakly dominated strategy since for no action of  $F_2$  will  $F_1$  make positive profits. But there is a sequence of equilibrium prices that converges from above to  $a + c_1$ , where in no such equilibrium a firm plays a weakly dominated strategy.

(u) *competitive case: The same as under legal unbundling. Set  $h_2 = 0$  and  $p_1 = p_2 = c_2 + a$  and let  $F_2$  get the whole market.*

In the monopoly case profits of the integrated firm are given by

$$\pi_{01}^m = (p_{01}^m - c_0 - c_1) Q(p_{01}^m)$$

In the competitive case its profits are given by

$$\pi_{01}^u = (a - c_0)Q(c_2 + a)$$

We find  $\frac{\partial(\pi_{01}^u - \pi_{01}^m)}{\partial c_1} > 0$  and  $\frac{\partial(\pi_{01}^u - \pi_{01}^m)}{\partial c_2} < 0$ . This means the competitive outcome occurs whenever the cost disadvantage of the own downstream operations is sufficiently large. With very inefficient own downstream operations, even the integrated firm might find it optimal to use  $F_2$  as its "sales channel" and live only on the upstream profits. In this case, clearly, sabotage would not make sense.

**Reverse legal unbundling** The following lemma shows that under reverse legal unbundling we either have the same market price as under separation or the monopoly price of an integrated firm. In fact, the worse of these two outcomes is realized, i.e. reverse legal unbundling is weakly worse than both separation and vertical integration.

**Lemma 5** *Under reverse legal unbundling the market price will be  $p = \max\{p_{01}^m, a + c_1\}$ . At price  $a + c_1$  firms  $F_1$  or  $F_2$  may produce, but at price  $p_{01}^m$ ,  $F_1$  will serve the whole market.*

The intuition is that under reverse legal unbundling,  $F_0$  maximizes joint profits and therefore has incentives for sabotage, and at the same time  $F_1$  only maximizes its own profits and therefore has no incentives to lower prices in order to increase output.

**Comparison of the four cases** Equipped with the solutions for the four cases we see that in this example legal unbundling is strictly superior to all other vertical structures (except for the competitive case of vertical integration, which yields an outcome identical to legal unbundling). Total output and consumer surplus are inversely related to the market price and therefore highest under legal unbundling. Profits of  $F_0$  are increasing in total output and hence also highest under legal unbundling. Production is efficient since  $F_2$  produces everything. Total welfare is increasing in total output as long as market prices are weakly above marginal cost of production  $c_0 + c_2$ , which is always the case. Thus we can state the following proposition:

**Proposition 7** *Under legal unbundling, prices are strictly lower, and total output, profit of  $F_0$ , consumer surplus and total welfare are strictly higher than under separation, reverse legal unbundling and the monopoly case of vertical integration. (In the competitive case of vertical integration, we have identical outcomes to legal unbundling).*

**Proof.** Immediate from comparing the outcomes of the four cases. ■

Finally, we turn to the question what happens when the double marginalization problem becomes negligible. This happens when  $a \rightarrow c_0$ , since then also in the case of separation the downstream firm calculates with (almost) the true marginal cost of the input good. Only under legal unbundling, the outcome will approach the welfare-optimal outcome, i.e. a first-best market price of  $c_0 + c_2$ . Under separation, the market price converges to a higher level of  $c_0 + c_1$  and under vertical integration always the sub-optimal monopoly case arises.

**Proposition 8** *For  $a \rightarrow c_0$ , the welfare-optimal outcome is approached under legal unbundling, but not under the other vertical structures.*

What is responsible for this striking difference is the induced output effect: In this example, it yields significantly larger quantities under legal unbundling, i.e. a significant downstream expansion effect, even when the double marginalization problem becomes arbitrarily small.<sup>13</sup>

## 5 Alternative regulatory pricing schemes

### 5.1 A general class of price regulation schemes where legal unbundling is optimal

So far we assumed that the regulator sets a linear access price  $a > c_0$ . Such linear access prices fulfill two conditions:

**(L1)**  $F_0$ 's profits  $\pi_0$  only depend on total output  $Q$ , but it does not matter which downstream firms produce how much of it.

**(L2)**  $F_0$ 's profits  $\pi_0$  are strictly increasing in total output  $Q$ .

---

<sup>13</sup>We also have extended the price competition example for allowing investments into marginal cost reduction. Legal unbundling then always yields the welfare-optimal level of investments. A proof is available from the authors upon request.

It turns out that our main results hold for every price regulation scheme that fulfills conditions (L1) and (L2). Let  $\alpha$  denote a price regulation scheme that fulfills (L1) and (L2). It determines how much money  $F_0$  receives when selling a total output  $Q$ , which we denote by a revenue function  $R(Q|\alpha)$ . Furthermore the scheme  $\alpha$  specifies how much downstream firms have to pay when actions  $x$  are chosen (which imply quantities  $q_i$ ). Thus profits are given by

$$\pi_0(x, h|\alpha) = R(Q(x, h)|\alpha) - c_0Q(x, h) - K + S$$

$$\pi_i(x, h|\alpha) = p_i(x, h)q_i(x, h) - C_i(x, h|\alpha) \text{ for } i = 1, \dots, n$$

To ensure that (L2) is fulfilled, we require that for all  $Q', Q$  with  $Q' > Q$  it holds that  $R(Q'|\alpha) - c_0Q' > R(Q|\alpha) - c_0Q$ .

For these more general regulatory schemes, which provide scope for additional desirable features, all the results proven in Section 3 and 4 still hold.

**Proposition 9** *The following results hold for every regulatory pricing scheme that fulfills (L1) and (L2): Proposition 1, 2, 4, 5 (first sentence) and 6.*

Our proofs for the mentioned propositions in the appendix all use the more general class of regulatory schemes illustrated in this section. Thus, we find that also for the larger class of regulatory schemes, legal unbundling can be seen as a golden mean between separation and vertical integration as it still delivers higher quantities and good investment incentives.

**Example** Consider the following example for such a pricing scheme: The regulator pays the upstream firm a linear access price  $a > c_0$ , but charges the downstream firms a two-part tariff with an access price equal to  $c_0$  plus a fixed fee. It is not necessary that the regulators' revenues have to equal expenditures, i.e. the higher marginal price paid to  $F_0$  may also be (partly) financed by subsidies.<sup>14</sup> This scheme has two benefits: First, a high access price  $a$  provides  $F_0$  strong incentives to maximize total output, which may be a good way to induce a sufficient high budget for capacity investments (see Section 3.1). Second, output in downstream markets is increased because, for the downstream firms, access is priced at its true marginal costs  $c_0$ .

Although under this regulatory scheme there is no double marginalization problem, output under legal unbundling may still be *strictly* above the output under

---

<sup>14</sup>Imposing high fixed fees can be problematic, because they may foreclose market entry by small downstream firms. In such cases subsidies may be preferred.

separation. For an illustration consider the price competition example from the previous section. If we assume that  $F_0$ 's markup  $a - c_0$  is financed by a subsidy (rather than a fixed fee), the analysis under this regulatory scheme is very similar to the original analysis and the results are straightforward: Under legal unbundling the entrant serves the whole market at the welfare-optimal price of  $c_0 + c_2$ , while under separation the entrant serves the market at a higher price of  $c_0 + c_1$ .

## 5.2 Inappropriateness of legal unbundling in the absence of access regulation

It is important to note that legal unbundling can yield very bad outcomes if access prices are unregulated. If  $F_0$  could freely decide on access prices, the strategy that maximizes upstream profits  $\pi_0$  would be to charge the incumbent  $F_1$  a very high access price and at the same time use all available measures to maximize  $F_1$ 's output, which could involve massive sabotage of downstream competitors.  $F_1$  is willing to pay such a high access price, because it gets the money back through  $F_0$ 's profits. Although in reality this mechanism will likely not appear in this extreme way, the basic incentive distortions are nevertheless likely to exist without price regulation. Along the lines of this example, a seemingly harmless rule that only prescribes a maximum access price for downstream competitors, but allows (or requires) higher access prices for the downstream incumbent may have quite negative outcomes. Thus whenever there is no access price regulation or the conditions (L1) and (L2) from above are violated, legal unbundling may lose its appealing properties.

## 6 Discussion

The analysis so far has shown that under rather general assumptions, legal unbundling exhibits desirable properties. Nevertheless, regulatory authorities often evaluate legal unbundling negatively. For instance, Neelie Kroes, European Competition Commissioner, expressed her views as follows:

Speaking very personally, I see only one way forward if we are to restore credibility and faith in the market. Europe has had enough of “Chinese walls” and quasiindependence. There has to be a structural

solution that once and for all separates infrastructure from supply and generation. In other words: ownership unbundling.<sup>15</sup>

A key concern in the European policy debate on vertical industry structures are investment incentives, in particular, for investments in cross-border transmission capacities. Such investments could pave the way for an integrated European market for electricity with an increased level of competition. Also for this issue, the EU Commission prefers vertical separation over legal unbundling. In the words of Commissioner Kroes:

As you will know, where interconnector capacity is scarce, it is auctioned off to the highest bidder, generating congestion revenues. If you look at our report, you will find that from 2001 to 2005, three German TSOs generated congestion revenues of over 400 million Euros. Of these revenues, under 30 million Euros were used to build new interconnectors- that's less than 10%!

In contrast, our experience shows that fully unbundled operators see clearer incentives for investment in interconnectivity, and act on those incentives, because they are focused on optimizing the use of the network.<sup>16</sup>

Although the European Commission views vertical separation (or ownership unbundling) as the most preferred vertical industry structure, it has positively considered an alternative structure with an "independent systems operator":

[...] the Commission has also examined an alternative approach known as 'ISO' or Independent System Operator, whereby the vertically integrated company maintains ownership of the network assets and receives a regulated return on them, but is not responsible for their operation, maintenance or development.<sup>17</sup>

<sup>17</sup>Neelie Kroes European Commissioner for Competition Policy 'A new European Energy Policy; reaping the benefits of open and competitive markets' Energy conference: E-world energy & water' Essen, 5th February 2007.

We believe that our analysis helps to understand better the effects from measures mentioned in the three quotes. We discuss the three points in turn.

First, our theoretical analysis assumed that legal unbundling works perfectly in separating the interests of the network company from the rest of the integrated group. This seems often not to be the case. Thus, it is important to understand what happens if the network company acts not completely independently and also takes into account the profits of the downstream firm  $F_1$ . This is analyzed in detail in Höffler and Kranz (2007). There it is shown that reducing the independence of the network firm yields the expected result of lowering total output. Put differently: more independence, i.e. a stronger regulation, increases the output. The optimum ownership structure therefore can depend on the strength of regulation. Höffler and Kranz (2007) show that if regulation is weak, vertical separation can indeed yield higher quantities than legal unbundling. However, if regulation is sufficiently strong, the results of the current paper apply (i.e. highest quantities under legal unbundling).

Since the effect of legal unbundling therefore seems to depend on the strength of regulation, the negative experiences of regulators may well be explained by insufficiently strong regulation. Although "sufficiently strong" regulation might not be implementable as such,<sup>18</sup> it might also be the case that intensifying regulation is possible and that such a strengthening of regulation will lead to a situation where legal unbundling is the preferred vertical structure. This could be done either by stronger legal requirements or by stricter implementation of existing rules. The second quote illustrates the point. Only since 2005 have German network companies been legally obliged to reinvest profits from the interconnector auctions<sup>19</sup> — thus, legal requirements have become more strict (irrespective of the question whether this particular tightening of regulation is sensible — below we propose an alternative approach to this problem). If the integrated companies still get away with not reinvesting, this would be due to a lack of enforcement of legal rules. The European Commission itself states that the existing rules are not yet fully implemented.<sup>20</sup> Thus, too little independence might at least partially be due to

---

<sup>18</sup>Although many legal rules exist to ensure independence (mentioned in section two), reaching perfect independence might nevertheless be difficult. For instance, even if the management of the network company today has no incentive to privilege the incumbent's downstream operations, career concerns within the group might bias decisions towards such a discriminatory behavior.

<sup>19</sup>In Germany, according to the *Netzzugangsverordnung* § 15 (3).

<sup>20</sup>That legal unbundling requirements are not yet fully implemented is explicitly noticed by the European Commission: "Even where Member States have adopted unbundling provisions

too weak implementation of existing regulation.

The resulting policy implication, therefore, is to strengthen regulation and to thoroughly implement the existing regulations in order to increase the independence before changing the regime towards full separation. Additionally, requiring legally unbundled firms to take on a minority outside investor, could help to increase independence. Consider a minority stake of, say 10%, of an institutional investor in the network company. The interest of the downstream firm in the network profits would still be large, such that beneficial effects of legal unbundling are still significant; at the same time, the investor has an interest in enforcing that the network company maximizes only its own profits.

The issue of investments, addressed in the second quote, is also interesting in light of our findings. From a theoretical perspective, completely separated network operators will also have incentives to provide only a monopoly amount of interconnector capacity — below the socially optimal level — if they directly receive the congestion revenues from the interconnector auctions.<sup>21</sup> Theory can also predict that legal unbundling can exaggerate this problem, since under legal unbundling the downstream incumbent may bid higher prices in the capacity auction in order to increase congestion revenues and thereby the profits of the network operator.

In this context, our discussion of more general regulatory schemes proves useful. One suggestion is to modify the capacity auction as follows: The regulator receives the revenues from the capacity auction and pays the network operator a regulated fixed access price for every unit that is sold in the auction. Then the network operator cannot influence the price it receives and therefore has no incentives to act like a capacity-reducing monopolist. Such a regime satisfies the assumptions of section 5.1; thus, we expect that legal unbundling will yield a higher output than separation under this modified regulation scheme.

Finally, consider the issue of independent system operators, subject to a rate of return regulation, mentioned in the third quote. The driving force for the benefits of legal unbundling over separation in our model is the fact that the downstream incumbent receives the network operator's profits and therefore wants to increase total output. But if, as suggested, the downstream incumbent only receives a regulated return on its network assets (independent of the profits from network

---

required under the Second Gas Directive, this does not mean that TSOs necessarily comply with them." (Sector Inquiry, Part 1, para 153, p. 57).

<sup>21</sup>See Höfler and Wittmann (2007) for a discussion of "supply reduction" in interconnector auctions.

operations), it has no incentive to increase total output, and the benefits of legal unbundling compared to separation would not arise.

To conclude the discussion, let us remark that we have left out some important issues. For instance, we have not discussed "vertical economies", i.e. possible efficiency gains from vertical integration from a technological or transaction cost point of view. The evidence for their existence is somewhat unclear, however. Fraquelli, Piacenza, and Vannoni (2005), Kwoka (2002), or Kaserman and Mayo (1991), for example, find evidence for more or less economically significant vertical economies. Although such economies of vertical integration may not be fully realized under legal unbundling, they should be realized to a larger extent than under complete separation. For example, the hold-up problem is likely to be reduced under legal unbundling, since  $F_1$  would in an investment decision take into account the surplus accruing to  $F_0$  and also has no interest in costly ex-post bargaining with  $F_0$ .

## 7 Conclusion

In this paper, we have demonstrated that, from a theoretical point, legal unbundling can be seen as a "golden mean" between complete separation and full vertical integration. If access prices are regulated and legal unbundling can ensure that the network company, controlling the essential facility, maximizes only the own profits, legal unbundling ensures higher quantities than the other vertical structures. This result is important, since higher quantities typically imply that also consumer surplus will be higher under legal unbundling.

A key message of our analysis is that, in addition to the sabotage effect, policy makers should also consider the *downstream expansion effect*: Under legal unbundling — compared to separation — the incumbent's downstream operations not only internalize the double marginalization problem but additionally can induce an output expansion by competitors. Most pronounced, in the case of downstream price competition, the incumbent prices more aggressively compared to a vertically separated downstream company, since this leads to a price reduction and higher quantities of downstream competitors and thereby to higher profits of the upstream operations.

We also analyzed investment incentives. Legal unbundling provides the better incentives for investments into the reduction of marginal costs and for the allocation of a given budget for capacity investments. Although, we cannot generally

rule out cases where legal unbundling leads to lower budgets for capacity investments, our results suggest that even in those cases legal unbundling may often be welfare superior. Concerning investments into network reliability, we argued that contractual solutions or appropriate regulation are needed under all vertical structures to ensure sufficient levels of investment.

We demonstrated that our results not only apply for linear access prices, but also for more general regulatory regimes. In the absence of price regulation, legal unbundling loses its appealing properties, however.

Policy recommendations cannot ignore the negative experiences regulators have made so far with legal unbundling. Our contribution is to offer a fairly general economic analysis of legal unbundling which helps to see potential benefits and to identify the necessary prerequisites for these benefits to apply. Our tentative policy recommendation would therefore be: Regulators should first try to implement legal unbundling rigorously, with particular emphasis on the independent decision making in the unbundled network unit, considering also to oblige legally unbundled network operators to take on minority shareholders. Only if experiences after full implementation are still negative, a regime shift towards full vertical separation should be considered.

# Appendix: Proofs

We prove Propositions 1, 3, 4 (first sentence), 5, 6 and Lemma 1 and 2 directly for the more general regulatory schemes introduced in section 5. The original propositions are a special case of this set-up, since a linear access price  $a > c_0$  fulfills conditions (L1) and (L2). We will generally use the notation  $Q^u$ ,  $Q^v$  and  $Q^s$  to denote the resulting outputs, under legal unbundling, vertical integration and separation, respectively and similarly  $h^u$ ,  $h^v$ ,  $h^s$  and  $x^u$ ,  $x^v$ ,  $x^s$  for firms' equilibrium choices in the different vertical structures.

Proof of Proposition 1: Under legal unbundling,  $F_0$  sets  $h$  in order to maximize upstream profits  $\pi_0$ , and by choosing the same sabotage strategy than under vertical integration,  $F_0$  can guarantee the same level of upstream profits — recall from the remark before Proposition 1 that the outcome under both structures will be the same whenever the sabotage strategy  $h$  is the same, even if downstream firms move simultaneously. Since  $\pi_0$  is strictly increasing in total output  $Q$  and vice versa, also total output under legal unbundling is always as least as high as under vertical integration.

Proof of Proposition 2: We show that  $F_0$  can guarantee a weakly higher total output under legal unbundling than under separation, i.e.  $Q^u \geq Q^s$  by choosing under legal unbundling the same sabotage strategy than the optimal sabotage strategy  $h^s$  under separation, i.e. by setting  $h^u = h^s$ . Under full separation, the incumbent  $F_1$  then chooses  $x^s$  to maximize  $\pi_1(x, h^s)$ , and under legal unbundling  $F_1$  chooses  $x^u$  to maximize  $\pi_1(x, h^s) + \pi_0(x, h^s)$ . Optimal choice by  $F_1$  thus implies

$$\pi_1(x^s, h^s) \geq \pi_1(x^u, h^s)$$

$$\pi_1(x^u, h^s) + \pi_0(x^u, h^s) \geq \pi_1(x^s, h^s) + \pi_0(x^s, h^s)$$

Adding both inequalities yields  $\pi_0(x^u, h^s) \geq \pi_0(x^s, h^s)$  and since upstream profits  $\pi_0$  are strictly increasing in total output, this implies that total output is weakly higher under legal unbundling than under separation, i.e.  $Q(x^u, h^s) \geq Q(x^s, h^s)$ . ■

Proof of Proposition 3: (Cournot)  $F_0$  can guarantee the same output under legal unbundling than under separation, an output of  $Q^u = Q^s$ , by setting  $h_1^u = h_1^s + (a - c_0)$  and hampering all other entrants in the same way as under vertical separation, i.e. setting  $h_i^u = h_i^s$  for all  $i = 2, \dots, n$ . With such hampering  $F_1$  maximizes under legal unbundling

$$\pi_1^s(q) + (a - c)q_2.$$

where  $\pi_1^s(q)$  denotes  $F_1$ 's profit function under vertical separation. The added term  $(a - c)q_2$  has no influence on  $F_1$ 's best reply function and therefore both firms have the same best reply functions as under vertical separation, leading to the same equilibrium outcome. ■

Proof of Proposition 4: If  $F_0$  sets the same sabotage strategy under separation than under reverse legal unbundling, i.e.  $h^s = h^r$  the total output and  $\pi_0$  will be the same, since downstream firms will act in the same way. Since under separation  $F_0$  wants to maximize total output and  $\pi_0$ , it will at least achieve output and  $\pi_0$  at least as high as under reverse legal unbundling, which is guaranteed by setting  $h^s = h^r$ . ■

Proof of Proposition 5: If under legal unbundling the same total amount would be invested as under separation (vertical integration), we only have an investment allocation problem, which is equivalent to our basic model as explained in the text. Thus, Proposition 1 applies and we know that  $\pi_0$  must be weakly higher under legal unbundling.  $F_0$  chooses a different investment level under legal unbundling than the optimal level under separation (vertical integration), only if this would lead to even larger net profits  $\pi_0 - I^u$ . Therefore the first sentence is true. The second sentence follows directly from the first result, under a linear access price  $a > c_0$ , by inserting  $\pi_0$  and rearranging the inequalities. ■

Proof of Lemma 1: Let  $c_0^a$  and  $c_0^b$  be two marginal costs with  $c_0^a > c_0^b$ . Let  $h^a$  denote  $F_0$ 's optimal  $h$  if marginal costs are  $c_a$ , and let  $x^a$  be the selected downstream equilibrium given  $h^a$  and  $c_a$ . We define  $h^a$  and  $x^b$  correspondingly. Under legal unbundling  $F_0$  wants to maximize total output  $Q$ . We show that  $F_0$  can guarantee  $Q^b \geq Q^a$  by setting  $h^b = h^a$ . Optimal choice by  $F_1$  then implies

$$\begin{aligned} \pi_1(x^a, h^a) + R(Q(x^a, h^a)) - c_0^a Q(x^a, h^a) &\geq \pi_1(x^b, h^a) + R(Q(x^b, h^a)) - c_0^a Q(x^b, h^a) \\ \pi_1(x^b, h^a) + R(Q(x^b, h^a)) - c_0^b Q(x^b, h^a) &\geq \pi_1(x^a, h^a) + R(Q(x^a, h^a)) - c_0^b Q(x^a, h^a) \end{aligned}$$

Adding up the two inequalities yields  $(c_0^a - c_0^b)Q(x^b, h^a) \geq (c_0^a - c_0^b)Q(x^a, h^a)$  and therefore  $Q(x^b, h^a) \geq Q(x^a, h^a)$ . ■

Proof of Proposition 6: Let  $I_a$  and  $I_b$  be two investment levels with  $I_a < I_b$  and let  $c_0^a$  and  $c_0^b$  with  $c_0^a > c_0^b$  be the resulting marginal costs. Generally subscripts or superscripts  $a$  and  $b$  index the investment level that is considered, while  $u, v$  and  $s$  index in the vertical structure in the common way. Let  $\Delta_{ab}^u := \pi_0^b(h_b^u, x_b^u) - \pi_0^a(h_a^u, x_a^u)$ ,  $\Delta_{ab}^s := \pi_0^b(h_b^s, x_b^s) - \pi_0^a(h_a^s, x_a^s)$  and  $\Delta_{ab}^v := \pi_{01}^b(h_b^v, x_b^v) - \pi_{01}^a(h_a^v, x_a^v)$  denote the changes in  $F_0$ 's objective function when marginal costs change from  $c_a$  to  $c_b$  (excluding the change in investment costs  $I_b - I_a$ ) under the different vertical

structures.

We will first derive a lower bound on  $\Delta_{ab}^u$ . Recall that  $\pi_0$  is strictly increasing in total output. Therefore  $Q(h_b^u, x_b^u)$  is the highest quantity that  $F_0$  can achieve with marginal costs  $c_0^b$  and by Lemma 1 also no higher quantity can be achieved under marginal costs  $c_0^a$ . Therefore  $\pi_0^a(h_a^u, x_a^u) \leq \pi_0^a(h_b^u, x_b^u)$ . Furthermore,  $\pi_0^b(h_b^u, x_b^u) - \pi_0^a(x_b^u, h_b^u) = (c_0^a - c_0^b) (Q(h_b^u, x_b^u))$ . Together with the definition of  $\Delta_{ab}^u$ , these two results imply

$$\Delta_{ab}^u \geq (c_0^a - c_0^b) Q(h_b^u, x_b^u).$$

We will now show that  $\Delta_{ab}^u - \Delta_{ab}^s \geq 0$  and  $\Delta_{ab}^u - \Delta_{ab}^v \geq 0$ , which implies that under legal unbundling we will always find weakly higher investment than under separation as well as integration.

(i)  $\Delta_{ab}^u - \Delta_{ab}^s \geq 0$  : Under complete separation, the total quantity  $Q^s$  is independent of  $F_0$ 's cost structure. Thus moving from  $c_a$  to  $c_b$  changes  $F_0$ 's profits by

$$\Delta_{ab}^s = (c_0^a - c_0^b) Q^s.$$

By Proposition 1,  $Q_b^u \geq Q^s$  and using the lower bound on  $\Delta_{ab}^u$  we find

$$\Delta_{ab}^u - \Delta_{ab}^s \geq (c_0^a - c_0^b) (Q_b^u - Q^s) \geq 0.$$

(ii)  $\Delta_{ab}^u - \Delta_{ab}^v \geq 0$  : Since under vertical integration both  $F_0$  and  $F_1$  want to maximize  $\pi_{01}$ , we have  $\pi_{01}^a(h_a^v, x_a^v) \geq \pi_{01}^a(h_b^v, x_b^v)$ . Furthermore,  $\pi_{01}^b(h_b^v, x_b^v) - \pi_{01}^a(h_b^v, x_b^v) = (c_0^a - c_0^b) Q(h_b^v, x_b^v)$ . Together with the definition of  $\Delta_{ab}^v$ , these two results imply  $\Delta_{ab}^v \leq (c_0^a - c_0^b) Q(h_b^v, x_b^v)$ . By Proposition 1, we have  $Q(h_b^u, x_b^u) \geq Q(h_b^v, x_b^v)$  and using the lower bound on  $\Delta_{ab}^u$ , we therefore find  $\Delta_{ab}^u - \Delta_{ab}^v \geq (c_0^a - c_0^b) (Q_b^u - Q_b^v) \geq 0$ . ■

Proof of Lemma 2: Standard case of price competition, see derivation in Section 4.

Proof of Lemma 3: At price  $c_2 + a$  the incumbent  $F_1$  prefers to give the whole market to  $F_2$ , since  $\pi_1$  is strictly negative for all prices below  $c_1 + a$ .  $F_0$  can guarantee this outcome by not sabotaging  $F_2$ , and therefore no equilibrium with a higher price than  $c_2 + a$  can exist. If  $a$  is large there could be cases, however, with an equilibrium price  $p'$  strictly between  $c_0 + c_1$  and  $c_2 + a$  where  $F_1$  gets the whole market. Although  $\pi_1$  would then be negative, joint profits  $\pi_1 + \pi_0$  could be higher than under the outcome where  $F_2$  gets the whole market at price  $c_2 + a$ , because output  $Q$  and upstream profits  $\pi_0$  are higher. Such an equilibrium with a price  $p' < c_2 + a$  can only arise, however, if the access price is Pareto-dominated

by a lower access price. To see this, consider an access price  $a' < a$  that fulfills  $a' + c_2 = p'$ . With such an access price,  $F_1$  would prefer to give the whole market to  $F_2$  at price  $p'$  instead of taking the market itself (since  $\pi_1$  is negative under  $p'$ ). Access price  $a'$  Pareto-dominates access price  $a$ , because no firm nor consumers are worse off and  $F_1$  is strictly better off under this outcome with access price  $a'$ . ■

Proof of Lemma 4: If  $F_1$  gets the market, then the optimal price is  $F_1$ 's monopoly price under costs  $c_1 + c_0$ . If  $F_2$  gets the total market it is optimal that this happens at the lowest possible price that  $F_2$  is ever willing to pay, i.e.  $c_2 + a$ . Joint profit  $\pi_{01}$  can also not be higher in a situation where both firms split total output at some price  $p$ . Since goods are perfect substitutes and marginal costs linear,  $\pi_{01}$  from splitting the market is at least as high if either only  $F_1$  or only  $F_2$  gets the total market at the same price  $p$ . ■

Proof of Lemma 5: Since under reverse legal unbundling  $F_1$  maximizes its own profits  $\pi_1$  and by assumption plays no weakly dominated strategy,  $F_1$  will never set a price below  $a + c_1$ , which implies that no equilibrium with a price below  $a + c_1$  exists. Since  $F_0$  maximizes joint profits  $\pi_0 + \pi_1$  and  $\pi_1$  is non-negative for all prices  $p \geq a + c_1$ ,  $F_0$  weakly prefers that  $F_1$  serves the whole market. Joint profit  $\pi_{01}$  is then maximized by the monopoly price would be  $p_{10}^m$ . If  $a + c_1 \leq p_{10}^m$ , then  $F_0$  can achieve this outcome by setting  $h_2$  such that  $a + c_2 + h_2 = p_{10}^m$ . Then  $F_1$  will a price equal to  $p_{10}^m$  and get the whole market. If  $a + c_1 > p_{10}^m$  the from all prices achievable in equilibrium the price  $p = a + c_1$  maximize  $\pi_{01}$ . This can be achieved by  $F_0$  setting  $h_2$  such that  $a + c_2 + h_2 = a + c_1$ . Whether  $F_1$  or  $F_2$  gets the market in this equilibrium does not matter. ■

Proof of Proposition 9: We prove the first sentence of the proposition for the case of legal unbundling; for vertical separation, the steps are similar. Total welfare, excluding investment costs, under legal unbundling is in our Bertrand model given by

$$W^u = CS(p^u) + p^u Q(p^u) - (c_0 - \delta + c_2) Q(p^u)$$

where the market price  $p^u = a + c_2$  does not depend on  $c_0$  and  $\delta$ . We thus find  $\frac{\partial W^u}{\partial \delta} = Q^u$  and  $\frac{\partial^2 W^u}{\partial \delta^2} = 0$ . Maximization of  $W^u(\delta) - I(\delta)$  is therefore equivalent to the first order condition

$$I'(\delta_u^o) = Q^u.$$

$F_0$  will choose its actual level of cost reduction  $\delta_u$  in order to maximize its profit  $(a - c_0 + \delta) Q(p^u) - I(\delta)$ . The profit-maximizing  $\delta_u$  fulfills the same first order

condition than  $\delta_u^o$ , i.e.

$$I'(\delta_u) = Q^u.$$

Therefore  $\delta_u = \delta_u^o$  and  $I_u = I(\delta_u) = I(\delta_u^o) = I_u^o$ .

The proof of the second sentence is by use of an example. Let  $Q(p) = 1 - p$  and  $I(\delta) = \frac{3}{4}\delta^2$  such that  $I'(\delta) = \frac{6}{4}\delta$ . Let  $c_1 = 0.3$ ,  $c_2 = 0.25$ ,  $c_0 = 0.5$  and  $a = 0.74$ . Then for all  $\delta$  the monopoly case will be selected under vertical integration since,  $1 - 0.8 + \delta - 2\sqrt{(0.24 + \delta)(0.01)} \geq 0$  for all  $\delta > 0$ . We will get  $\delta_m^o = 0.2$  and  $\delta_m = 0.1$ . As well as  $\frac{I_m^o}{I_m} = 4$ . This means the optimal investment would be 4 times higher than the actual investment under vertical integration. ■
