

# Quality Uncertainty in Vertical Relations: Mutual Dependency Mitigates Inefficiencies

Pio Baake    Vanessa von Schlippenbach

DIW Berlin

## Quality Uncertainty in Vertical Relations

- ▶ Increase of product recalls due to product failures involving safety or health risks for consumers
  - ▶ In the U.S. food and toys industry number of recalls almost doubled
  - ▶ In the German automotive industry even tripled
- ▶ Product failures can be caused at various stages of the value chain
- ▶ However, manufacturing defaults have gained in importance
  - ▶ DaimlerChrysler recalled 1.3 million cars for checking battery control unit software + voltage regulator in the alternator (2005)
  - ▶ Mattel recalled 18 million toys because of small dislodgeable magnets as well as toxic lead paint (2007)
  - ▶ Arla and Nestle recalled their products worldwide because of the Chinese melamine scandale (2008)
  - ▶ Irish Republic recalled domestically-produced meat because of dioxin contaminated feed (2008)
- ▶ Problem: Consumers tend to attribute quality defects mainly to brands or retailers.

## Main Objective & Result

### **Objective:**

Examining the impact of quality uncertainty and potential reputation losses in the downstream market on the bargaining relation between suppliers and buyers

### **Result:**

Efficient delivery contracts in intermediate goods markets as well as efficient quality decisions are more likely the higher the mutual dependency in vertical relations

## Related Literature

### Buyer Power

- ▶ Wide literature on sources of buyer power (i.e. Katz 1987, Inderst-Shaffer 2007, Snyder 1996)
- ▶ Some papers related to efficiency effects of buyer power:
  - ▶ Inderst-Wey (2003, 2007): increase of upstream investment incentives
  - ▶ Montez (2008): downstream merger → higher capacity choice upstream
  - ▶ Inderst-Shaffer (2007): retail merger reduces upstream variety
  - ▶ Battigalli et al. (2007): buyer power weakens supplier's incentives to invest in quality
- ▶ Our contribution: Mutual dependency enhances efficiency of a vertical structure

### Umbrella Branding

- ▶ Literature is mainly related to downstream markets (i.e. Choi 1998, Andersson 2002, Cabral 2008)
- ▶ Our contribution: Umbrella branding can enhance efficiency of vertical relations

# The Model

## Structure & Timing

### Structure:

- ▶ Repeated game with imperfect information
- ▶ Downstream firm  $D$  offers two goods  $x$  and  $y$  (complements)
- ▶ Upstream firm  $U$  offers good  $x$  ( $y$  is offered competitively)
- ▶ Quality of good  $x$  is stochastically determined in each period

### Timing

1.  $D$  decides on target quality  $\bar{\theta}$  for good  $x$
2.  $D$  and  $U$  negotiate a menu of two-part tariff delivery contracts
3.  $U$  can invest in order to increase the probability of reaching  $\bar{\theta}$
4.  $U$  observes the actual quality  $\theta$  and announces a quality  $\hat{\theta}$
5.  $D$  sets the consumer prices conditional on  $\hat{\theta}$   
(and selects the respective delivery contract)

## Assumptions

► **Demand:**

$$X(p, q, \theta) \text{ with } X_p, X_{pp} < 0 < X_\theta \text{ and } X_q < 0$$

$$Y(q, p, \theta) \text{ with } Y_q, Y_{qq} < 0 < Y_\theta \text{ and } Y_p < 0.$$

► **Quality:**

$$\theta \in \{\underline{\theta}, \bar{\theta}\} \text{ with } \underline{\theta} < \bar{\theta}$$

$$\theta = \begin{cases} \bar{\theta} & \text{with probability } \rho(e, \bar{\theta}) \\ \underline{\theta} & \text{with probability } 1 - \rho(e, \bar{\theta}) \end{cases}$$

► **Probability:**

$$\rho(e, \bar{\theta}) : \rho_{\bar{\theta}} < 0 < \rho_e \text{ and } \rho_{e\bar{\theta}} < 0$$

► **Effort costs:**

$$c(e) : c', c'' > 0$$

## Assumptions (cont'd)

- ▶ **Negotiated Delivery Tariffs:**

$$T(w, F, \hat{\theta}) = \begin{cases} (\bar{w}, \bar{F}) & \text{if } \hat{\theta} = \bar{\theta} \\ (\underline{w}, \underline{F}) & \text{if } \hat{\theta} = \underline{\theta} \end{cases} .$$

- ▶ **Focus on tariffs such that firm  $U$  will announce truthfully:**

$$\hat{\theta}(\theta, T(\cdot)) = \theta$$

## Expected Profits per Period

### Upstream firm:

$$E\pi^U = \rho(e, \bar{\theta})\bar{\pi}^U + (1 - \rho(e, \bar{\theta}))\underline{\pi}^U - c(e)$$

$$\text{with : } \bar{\pi}^U = \bar{w}\bar{X} + \bar{F} \text{ and } \bar{X} := X(p, q, \bar{\theta})$$

$$\text{with : } \underline{\pi}^U = \underline{w}\underline{X} + \underline{F} \text{ and } \underline{X} := X(p, q, \underline{\theta}).$$

### Downstream firm:

$$E\pi^D = \rho(e, \bar{\theta})\bar{\pi}^D + (1 - \rho(e, \bar{\theta}))\underline{\pi}^D$$

$$\text{with : } \bar{\pi}^D = (p - \bar{w})\bar{X} + q\bar{Y} - \bar{F} \text{ and } \bar{Y} := Y(p, q, \bar{\theta})$$

$$\text{with : } \underline{\pi}^D = (p - \underline{w})\underline{X} + q\underline{Y} - \underline{F} \text{ and } \underline{Y} := Y(p, q, \underline{\theta}).$$

# Solving the Model

# Prices

**Downstream firm's profit  $\pi^D$  :**

$$\begin{aligned}\pi^D(\cdot) &= (p - w)X(\cdot, \theta) + qY(\cdot, \theta) - F \\ &\rightarrow (p, q) = \arg \max \pi^D(\cdot)\end{aligned}$$

## Announcement

**Truthful announcement by firm  $U$  as long as**

$$IC_1 : \underline{\pi}^U + \frac{1}{\delta} \overline{E\pi^U} \geq \overline{w}X(\overline{p}, \overline{q}, \underline{\theta}) + \overline{F} + \frac{1}{\delta} \Gamma^U$$

$$IC_2 : \overline{\pi}^U + \frac{1}{\delta} \overline{E\pi^U} \geq \underline{w}X(\underline{p}, \underline{q}, \overline{\theta}) + \underline{F} + \frac{1}{\delta} \Gamma^U.$$

- $\delta$  : = Interest rate
- $\overline{E\pi^U}$  : = Firm  $U$ 's continuation profits
- $\Gamma^U$  : = Outside option of firm  $U$

## Investment

- ▶ Firm  $U$ 's optimal effort  $e^*(\cdot)$  is implicitly given by

$$E\pi^U = \rho(e, \bar{\theta})\bar{\pi}^U + (1 - \rho(e, \bar{\theta}))\underline{\pi}^U - c(e)$$

$$e^*(\cdot) : \rho_e = \frac{c'(e)}{\Delta\pi^U} \text{ with } \Delta\pi^U := \bar{\pi}^U - \underline{\pi}^U.$$

- ▶ Effort increases in  $\bar{w}$ .

## Delivery Tariffs

- **Bargaining over delivery tariffs: Nash-Product in each period**

$$N = \left[ E\pi^D(\cdot) - \Gamma^D + \frac{1}{\delta} \left( \overline{E\pi^D} - \Gamma^D \right) \right] \left[ E\pi^U(\cdot) - \Gamma^U + \frac{1}{\delta} \left( \overline{E\pi^U} - \Gamma^U \right) \right]$$

$$E\pi^D : = \rho(\cdot)\bar{\pi}^D + (1 - \rho(\cdot))\underline{\pi}^D$$

$$\Gamma^D : = \tilde{q}Y(\tilde{q}, \infty, \cdot) \text{ with } \tilde{q} := \arg \max qY(q, \infty, \cdot)$$

$$\Gamma^U : = \text{Outside option of firm } U$$

- **Note: We consider profits over all periods.**

## Unconstrained Solution

► **Delivery tariffs:**

$$\underline{w}^* = \overline{w}^* = 0$$

$$\overline{F}^* - \underline{F}^* = \overline{p}\overline{X} + \overline{q}\overline{Y} - (\underline{p}\underline{X} + \underline{q}\underline{Y})$$

$$\text{Implying: } \overline{\pi}^D - \underline{\pi}^D = 0$$

- **Thus, risk is fully borne by upstream firm such that effort decision is efficient.**

## Unconstrained Solution (cont'd)

- ▶ **Optimal target quality  $\bar{\theta}^*$  implicitly given by**

$$\rho [\bar{p}\bar{X}_{\bar{\theta}} + \bar{q}\bar{Y}_{\bar{\theta}}] + \rho_{\bar{\theta}} [\bar{p}\bar{X} + \bar{q}\bar{Y} - (\underline{p}\underline{X} + \underline{q}\underline{Y})] = 0$$

### Proposition

*If the incentive constraints are not binding,  
the bargaining outcome is efficient.*

## Constrained Solution

### ▶ Binding constraint

$$IC_1 : \underline{\pi}^U + \frac{1}{\delta} \overline{E\pi^U} \geq \overline{w}X(\overline{p}, \overline{q}, \underline{\theta}) + \overline{F} + \frac{1}{\delta} \Gamma^U$$

$$\text{Implying} : \overline{F} = \underline{\pi}^U - \overline{w}X(\overline{p}, \overline{q}, \underline{\theta}) + \frac{1}{\delta} (\overline{E\pi^U} - \Gamma^U)$$

### ▶ Fixed Fees

- ▶ Used to ensure truthful announcement and to allocate joint surplus
- ▶ Allocation of risk and thus effort decision inefficient

### ▶ Wholesale Prices

- ▶  $\underline{w}^* = 0, \overline{w}^* > 0$
- ▶ Note: higher  $\overline{w}$  implies higher effort

### ▶ Target Quality

- ▶ Optimal target quality  $\overline{\theta}^*$  distorted (either too high or too low)
- ▶  $\overline{\theta}^*$  is more likely to be inefficiently low (high), the lower (higher)  $\overline{w}$

## Constrained Solution (cont'd)

### Corollary:

*Mutual dependencies in terms of low outside options may help to mitigate high wholesale and retail prices and may lead to more efficient quality decisions.*

- ▶  $\Gamma^U$  = inverse measure of buyer power
- ▶ Thus, buyer power may not only cause lower wholesale and retail prices it may also lead to more efficient quality decisions.
- ▶ Low values of  $\Gamma^D$  can result from high complementarities or the use of umbrella-branding.
- ▶ Hence, as long as umbrella-branding increases the interdependency between the products offered by the downstream firm it can also induce lower wholesale prices.

# Example

## Assumptions

- ▶ **Dixit utility function:**

$$U(x, y, \theta) = \left(1 + \frac{1}{4}\sqrt{\theta}\right)x + y - \frac{1}{2}(x^2 + y^2 - 2\sigma xy) - px - qy,$$

- ▶ **Probability and effort costs:**

$$\begin{aligned}\rho(e, \theta) &= \min \left\{ \frac{e}{1 + \theta}, 1 \right\} \\ c(e) &= \frac{e^2}{2} \\ \delta &= 0.1\end{aligned}$$

## Unconstrained Solution

- ▶  $\bar{\theta}^*$  decreases in  $\sigma$ 
  - ▶ Trade off from higher  $\bar{\theta}^*$ : Marginal revenue from  $\theta$  increases in  $\sigma$ , while  $U$ 's effort level is decreasing in  $\bar{\theta}$  if  $\bar{w} = 0$ .
- ▶  $IC_2$  is binding for all  $\Gamma^U > \Gamma^K(\sigma)$ 
  - ▶  $\Gamma^{K'}(\sigma) > 0$  since joint profits are increasing in  $\sigma$

Optimal target quality and critical outside option of firm  $U$

## Constrained Solution

- ▶  $\Gamma^U$  unambiguously increases the optimal wholesale price  $\bar{w}^*$
- ▶  $\bar{\theta}^*$  is not monotone in  $\Gamma^U$ 
  - ▶ First decrease of  $\bar{\theta}^*$  in order to avoid inefficient low effort, then increase because of higher  $\bar{w}^*$  and thus higher effort investment with high  $\bar{\theta}$ .

Optimal target quality for  $\sigma = 0.5$

## Welfare

- Both relatively low and high target qualities combined with positive  $\bar{w}^*$  reduce expected welfare.

Expected Welfare in  $\Gamma$  for  $\sigma = 0.5$

# Conclusion

# Conclusion

## ► Analysis of a simple vertical structure:

- Good's quality is stochastically determined and private information of  $U$
- Delivery contracts negotiated and contingent on actual quality

## ► Results:

- Delivery conditions as well as target quality are distorted when  $U$ 's incentives to deviate from truthful announcement are high enough.
- Mutual dependency increases efficiency of the vertical structure.
- Thus, buyer power leads to lower wholesale prices and more efficient quality decisions.
- Furthermore: Relation specific investments upstream as well as umbrella branding at the downstream level may enhance the efficiency of the vertical chain.
- Finally, outsourcing more attractive the more both firms depend on their interaction.
