Abstract

We examine the diffusion of different types of information through email networks and the effects of these diffusion patterns on the performance of information workers. In particular, we ask: What predicts the likelihood of individuals becoming aware of a new piece of information, and how quickly they obtain it? Do different types of information exhibit different diffusion patterns, and do different characteristics of social structure, relationships and individuals in turn affect access to different kinds of information? Does better access to information in turn predict an individual's ability to complete projects or generate revenue? We characterize the social network of a medium sized executive recruiting firm using accounting data on project co-work relationships and ten months of email traffic. We identify two distinct types of information diffusing over this network – 'event news' and 'discussion topics' – by their usage characteristics, and observe several thousand diffusion processes of each type of information. We find the diffusion of news, which is characterized by a spike in communication and rapid, pervasive diffusion through the organization, is influenced by demographic and network factors but not by functional relationships (e.g. prior co-work, authority) or the strength of ties. In contrast, the diffusion of discussion topics, which exhibit shallow diffusion characterized by 'back-and-forth' conversation, is heavily influenced by functional relationships and the strength of ties, as well as demographic and network factors. Discussion topics are more likely to diffuse vertically up and down the organizational hierarchy, across relationships with a prior working history, and across stronger ties, while news is more likely to diffuse laterally as well as vertically, and without regard to the strength or function of relationships. We also find access to information strongly predicts project completion and revenue generation. The effects are economically significant: Each additional new "word seen" by an individual is correlated with about $70 of additional revenue generated by that individual. Our findings provide some of the first evidence of the economic significance and nature of information diffusion in email networks.

Keywords: Email, Social Networks, Information Diffusion, Productivity

Introduction

The process of information diffusion through social groups lies at the heart of numerous business phenomena in industrial organization, strategy, productivity, finance, marketing, and innovation. Theories on subjects as wide ranging as the diffusion of innovations (e.g. Rogers 1995), dynamic trading behavior (e.g. Hirshleifer et. al. 1994), and the mechanics of word of mouth marketing (e.g. Dellarocas 2003), rely on information diffusion as a central theoretical building block, making important assumptions about how information spreads between individuals. Timely access to strategic information, innovative ideas, or current news can also highlight hidden opportunities, provide negotiating leverage (Burt 1992), promote innovation (Burt 2004), and ultimately drive economic performance (Reagans & Zuckerman 2001, Hansen 2002, Aral, Brynjolfsson & Van Alstyne 2006). But, while theories based on information diffusion proliferate, empirical evidence on how information spreads through social groups and the ultimate economic effects of information diffusion remain scarce. Combining economic methods with computer science data capture is an approach uniquely well positioned to address this gap.

Diffusion studies are typically theoretical (Jackson & Yariv 2005) or simulation based, or observe adoption or purchase decisions rather than the actual flow of information. Existing theory focuses mainly on which global social structures maximize diffusion, and although we know that transfers of certain types of information are easier than others (Von Hippel 1998), diffusion studies typically treat information as homogenous, making variation in diffusion patterns across different information types difficult to theorize. These gaps in research give rise to a natural set of questions about the movement of information through populations: How does information diffuse through a given social group? What makes someone more likely to be exposed to an idea as it spreads? Do different types of information diffuse differently? Can we explicitly link access to novel information to changes in performance?

We study the movement of different types of information through one organization over two years to understand how it diffuses and how diffusion patterns affect the relative productivity of information workers. We argue that the dual effect of content and structure jointly predict the diffusion path of a given piece of information – that both the type of information and the types of social relationships or structures through which it passes affect the diffusion path. While one type of information may be more likely to diffuse upward through the organizational hierarchy or strictly across functional relationships, another may diffuse laterally or without regard to function or hierarchy. To test our theory, we characterize the social network of a medium sized executive recruiting firm using ten months of email data and accounting data on project co-work relationships. We identify two types of information diffusing through this network – 'event news' and 'discussion topics' – by their usage characteristics, and observe several thousand diffusion processes of each type. We then test the effects of network, functional, organizational and demographic characteristics of dyadic relationships and individuals on the likelihood of receiving each type of information and receiving it sooner, and the effects of access to information on performance.

Our results demonstrate that the diffusion of news, characterized by a spike in communication and rapid, pervasive diffusion through the organization, is influenced by demographic and network factors but not by functional relationships (e.g. prior co-work, authority) or the strength of ties. In contrast, diffusion of discussion topics, which exhibit more shallow diffusion characterized by 'back-and-forth' conversation, is heavily influenced by functional relationships and the strength of ties, as well as demographic and network factors. Discussion topics are more likely to diffuse vertically up and down the organizational hierarchy, across relationships with a prior working history, and across stronger ties, while news is more likely to diffuse laterally as well as vertically, and without regard to the strength or function of relationships. We also find that access to information strongly predicts employees' productivity. Timely access to more information predicts the number of projects completed by each individual and the amount of revenue each person generates holding constant demographic and traditional human capital characteristics. These effects are economically significant, with each additional "word seen" by an individual correlated with about $70 of additional revenue generated. Conversely, productivity suffers noticeably the longer it takes an employee to receive information. Our findings provide some of the first evidence of the economic significance of information diffusion in email networks.

Theory & Literature
Information Diffusion – Its Importance & the Current State of Knowledge

Theories of *innovation* diffusion (e.g. Rogers 1995) ultimately rely on *information* diffusion as a central mechanism driving adoption decisions. Potential adopters are exposed to new innovations and are convinced to adopt through "processes by which participants create and share information with one another in order to reach mutual understanding" (Rogers 1995: 17). As Rogers (1995: 17-18) describes, "the essence of the diffusion process is the information exchange through which an individual communicates a new idea to one or several others." Information diffusion also underlies several theories of word of mouth marketing and dynamical trading behavior in

financial markets. Hirshleifer et. al. (1994) demonstrate that temporal asymmetries in the diffusion of information to traders create abnormal profits for the informed and explain seemingly irrational trading equilibria, such as "herding" or outcomes based on "follow the leader" strategies. Yet, in these models temporal asymmetries in information acquisition are taken as given, and how and why these systematic asymmetries arise remains unknown.

Current information diffusion studies typically rely on computer simulations of a handful of agents (e.g. Buskens & Yamaguchi 1999, Newman et. al. 2002, Reagans & Zuckerman 2006) and treat information as homogeneous (e.g. Buskens & Yamaguchi 1999, Wu et. al. 2004, Newman et. al. 2002, Reagans & Zuckerman 2006). Much of current literature concerns maximizing the spread of influence through a social network by identifying influential nodes likely to "trigger" pervasive information cascades (e.g. Domingos & Richardson 2001, Newman et. al. 2002, Kempe, Kleinberg, Tardos 2003), or enumerating characteristics of information cascades (e.g. Leskovec, Singh, Kleinberg 2006).[1] A current focus on global network properties that maximize information diffusion (e.g. Watts & Stogatz 1998) deemphasizes predictors of access to information cascades and their economic consequences.[2] In addition, information homogeneity assumptions are problematic in light of evidence demonstrating differences in transfer effectiveness across different types of information (Reagans & McEvily 2003). Some information is simply "stickier" (Von Hippel 1998) and more difficult to transfer (Hansen 1999) due to its specificity (Nelson 1990), complexity (Uzzi 1997, Hansen 1999), the amount of related knowledge of the receiver (Cohen & Levinthal 1990, Hansen 2002), or the degree to which information is declarative or procedural (Cohen & Bacdayan 1994). These factors make it unlikely that all types of information exhibit uniform transfer rates or diffusion patterns across different social structures. Although there is a body of literature on knowledge transfers and performance (e.g. Reagans & Zuckerman 2001), most of this work remains "agnostic with respect to content" (Hansen 1999: 83) and only considers whether knowledge is flowing rather than the type of knowledge being transferred. A related literature examines conditions under which knowledge and information flow efficiently between business units and individuals (e.g. Hansen 1999, 2002, Reagans & McEvily 2003), but this work focuses on dyadic transfers of information rather than on the diffusion paths of information through a population.

In the next section, we develop theory suggesting that the strength and function of social relationships, geographic proximity, organizational boundaries, and hierarchy, authority and status differences across social groups affect the movement of information, and have different effects across different types of information. In so doing, we propose three extensions to current work. First, in addition to network structures, we argue that there are hierarchal, demographic and task based drivers of information diffusion. For example, information may diffuse more readily vertically (or laterally) through an organizational hierarchy due to authority or status differences, or more quickly through functional relationships than strong ties per se. Second, we hypothesize that different types of information content diffuse differently. Third, we argue that content and structure jointly predict the diffusion path information - that different social and structural factors will govern the diffusion of different types of information. We then argue that timely access to novel information should improve decisions and productivity. Employees who are aware of new ideas and information are better able to solve problems, improve decisions and conclude projects.

Social Drivers of Information Diffusion

We hypothesize four categories of factors that may impact information dynamics in organizations:

1. *Demography & Demographic Distance*. Individuals' demographic characteristics and dissimilarity are likely to affect social choices about information seeking and information transmission. Similar individuals tend to flock together in social relationships (McPherson, Smith-Loving, & Cook 2001), creating parity in perspectives, information and resources across demographically similar individuals in organizations (Burt 1992, Reagans & Zuckerman 2001). Demographic diversity can also create social divisions and tension (Pfeffer 1983), reducing the likelihood that individuals will go to each other for advice or pass information (Blau 1977). We therefore measure

---

[1] Leskovec, Singh & Kleinberg (2006: 1) find that cascades in online recommendation networks "tend to be shallow, but occasionally large bursts of propagation appear" such that "the distribution of cascade sizes is approximately heavy-tailed."
[2] Two core models have emerged to explain the diffusion of influence and contagion. Threshold models posit that individuals adopt innovations after surpassing their own private "threshold" (e.g. Granovetter 1978, Schelling 1978). Cascade models posit that each time an adjacent individual adopts, the focal actor adopts with some probability that is a function of their relationship (e.g. Kempe, Kleinberg, Tardos 2003). While both models assume an information transmission between adopters and non-adopters, they rarely specify the nature of the information or the conditions under which exchanges take place. Rather, the diffusion process is typically tested under various assumptions about the distribution of thresholds or dyadic adoption probabilities in the population. In fact, as Kempe, Kleinberg, Tardos (2003: 2) explain "the fact that [thresholds] are randomly selected is intended to model our lack of knowledge of their values."

the demographic characteristics of individuals and the demographic dissimilarity of pairs of individuals focusing on age, gender, and education, three of the most important variables in organizational demography.[3]

2. *Organizational Hierarchy*. Formal structures define reporting relationships and work dependencies that necessitate communication and coordination (Mintzberg 1979). Mangers and employees frequently communicate to manage administrative tasks even when they are not working on the same projects, and the importance of notification for accountability, and recognition for upward mobility encourages dialogue and information exchange along hierarchical lines. Embedded within formal organizational hierarchies are gradients of status and authority that may also guide information flows (Blau 1977). As project teams in our organization are organized hierarchically, task related information is likely to flow vertically rather than laterally across organizational rank. We therefore measure each individual's position in the organizational hierarchy (e.g. partner, consultant, and researcher).

3. *Functional Task Characteristics*. Working relationships are conduits of information flow. They necessitate exchanges of task related information and create relatively stable ties that individuals rely on for future projects. However, relationships can decay over time (Burt 2002), and repeated relationships are more likely to create long term conduits through which information diffuses. People can also seek advice laterally from peers as distinct from seeking direction vertically from superiors. We therefore measure the strength of project co-work relationships by the number of projects employees have worked on together. We also know from the literature on absorptive capacity (Cohen & Levinthal 1990) that related knowledge helps individuals consume new information, and individuals in related fields and of related expertise are more likely to swim in the same pools of information. We therefore also measure whether or not employees work in the same expertise area. We expect information to diffuse more easily between employees with the same industry tenure, who have been through similar work related milestones and may already be familiar with one another through industry relationships (Pfeffer 1983). Status and authority differences also may prevent less experienced workers from soliciting or sharing information across industry tenure gradients while more experienced workers, less constrained by status and authority differences, may rely on other experienced workers for information.

4. *Tie & Network Characteristics*. Informal networks are also likely to impact information diffusion in organizations. A vast literature treats the relationship between social network structure and performance (e.g. Burt 1992, Cummings & Cross 2003). Although most of this work does not measure information flows explicitly, evidence of a relationship between performance and network structure is typically assumed to be due in part to the information flowing between connected actors (Burt 1992, Reagans & Zuckerman 2001). As individuals interact more frequently, they are likely to pass information to one another. We therefore measure the *strength of communication ties* by the total volume of email passing between each pair of individuals in our network. Other studies demonstrate that '*betweenness centrality*' $B(n_i)$ (Freeman 1979),[4] which measures the probability that the individual will fall on the shortest path between any two other individuals linked by email communication, predicts the total amount of knowledge acquired from other parts of the network (Hansen 1999), and that actors with high network *constraint* C_i (Burt 1992: 55)[5] (a proxy for the redundancy of contacts) are less privy to new information (Burt 1992). We therefore measure individuals' betweenness centrality and their constraint as follows:

$$B(n_i) = \sum_{j<k} g_{jk}(n_i) \Big/ g_{jk} \;; \qquad\qquad C_i = \sum_j \left(p_{ij} + \sum_q p_{iq} p_{qj} \right)^2, \quad q \neq i, j.$$

5. *Geographic Distance*. Finally, a great deal of evidence links physical proximity to communication between actors (e.g. Allen 1977). In the case of email, geographic distance may be associated with more email communication between actors who find it costly to communicate face to face. We therefore measure *physical proximity* by whether two people work in the same office.

Dimensions of Information Content

Characteristics of information content are also likely to affect diffusion patterns. Certain types of information are "stickier" and have higher transfer costs (Von Hippel 1998). We describe two contrasting information types, 'event news' and 'discussion topics,' which serve as vignettes for comparison.[6]

---

[3] We do not have access to race or organizational tenure variables (although we do measure industry tenure).

[4] Where g_{jk} is the number of geodesic paths linking *j* and *k* and $g_{jk}(n_i)$ is the number of geodesic paths linking *j* and *k* involving *i*.

[5] Where $p_{ij} + \sum p_{iq} p_{qj}$ measures the proportion of *i*'s contacts directly or indirectly involving *j*; C_i sums across all of *i*'s contacts.

[6] These vignettes are intended as archetypes, not mutually exclusive categories. These archetypes evoke underlying usage characteristics of information that are likely correlated with diffusion patterns of particular words in email. Our contention is that

Event News. We define 'event news' as simple, declarative, factual information that is likely triggered by an external event and is of general interest to many people in the organization. In the context of our research site, employees may learn of forthcoming layoffs at a source company, a forthcoming change in company policy, or a significant change in top management through a rapid pervasive information cascade that travels quickly and pervasively throughout the organization. Such information is likely simple, declarative and factual, informing recipients of an event that has or will soon take place. It is also likely to be of general interest to most employees in the firm and be widely shared among many people and across organizational and hierarchical boundaries.

Discussion Topics. We define 'discussion topics' as more specific, complex, and procedural, characterized by back and forth discussion of interest to limited, specialized groups. At this firm, work groups discuss particular projects, and most frequently have back and forth dialog about particular candidates or clients. Candidate names may volley back and forth as individual merits for a particular job are being considered. Teams specializing in filling nursing job vacancies in the south eastern United States may circulate names among other recruiters who specialize in the same type of job in the same region.

Theories of information transfer support our distinctions between event news and discussion topics. Complex knowledge is more difficult and costly to transfer requiring strong dyadic ties for effective transfers (Hansen 1999). A theoretical distinction is also made between declarative and procedural information (Cohen & Bacdayan 1994, Bulkley & Van Alstyne 2005), with the former consisting of "facts, propositions and events," and the later of information about how to accomplish "tasks, activities or routines" (Cohen & Bacdayan 1994: 557). We argue that event news is more likely to be simple and declarative, and thus more easily transferred widely among different types of people. Nelson (1990) and Von Hippel (1998) also make the distinction between "specific" and "generic" information and knowledge, arguing that, in contrast to the specific, "generic knowledge not only tends to be germane to a wide variety of uses and users. Such knowledge is the stock in trade of professionals in a field … so that when new generic knowledge is created anywhere, it is relatively costless to communicate to other professionals" (Nelson 1990: 11-12, as quoted in Von Hippel 1998: 431).[7] Finally, transfers of information and knowledge are more effective among individuals with related knowledge (Cohen & Levinthal 1990, Hansen 2002). Those with similar expertise or specialization are more likely to share information due to their shared common interests and their ability to more effectively communicate ideas based on their "common ground" (Cramton 1991). We therefore hypothesize diffusion of event news will be driven by demographic and network factors that constrain interactions due to homophily and network constraints.

> H1: *Access to event news is driven by demographic similarity, and structural characteristics of network position such as betweenness centrality, constraint and path length.*

On the other hand, information passed back and forth amongst small groups is likely to be task specific and relevant to those socially and organizationally proximate to the originator. At our research site, since work groups are organized vertically along the organizational hierarchy, with teams composed of one member from each organizational level, we expect task related information to be passed vertically up and down the organizational hierarchy, rather than laterally between members of the same organizational level. We hypothesize that diffusion of discussion topics, is driven not only by demographic and network factors, but also by project co-work relationships and organizational hierarchy.

> H2: *Access to discussion topics is driven by demographic similarity, and structural characteristics of network position such as betweenness centrality, constraint and path length, as well as by task characteristics and organizational hierarchy.*

Information Access & Productivity

Both information economics and social network theory contend that timely access to novel information can help employees make faster, higher quality decisions and improve their relative productivity and performance. Reductions in uncertainty can improve resource allocations and decision making, and reduce delay costs (Cyert &

---

these types information are likely to diffuse in specific patterns, and that words exhibiting these patterns proxy for the characteristics we describe. The relationship between the types of information described and the diffusion patterns observed is not critical. Our goal is to demonstrate that different characteristics of people, relationships, and social structure affect access to information with different aggregate diffusion patterns.

[7] While an important distinction exists between knowledge and information, we assume characteristics that make knowledge complex and costly to transfer influence characteristics of information employees in this firm send and receive.

March 1963, Galbraith 1973). In our context, precise, timely information about the candidate pool can reduce time wasted interviewing candidates unsuitable for a given search. Timely information also tempers risk aversion, enabling actors to make appropriate decisions faster (Arrow 1962). Reductions in uncertainty help recruiters place the right candidates in front of the right clients at the right time, increasing the likelihood of concluding searches faster, improving contract execution per unit time. Information is also valuable due to its local scarcity. Actors with scarce, novel information in a given network neighborhood are better positioned to broker opportunities, barter for future favors, or apply information to problems that are intractable given local knowledge (e.g. Burt 1992). For example, the name of an eligible candidate may enter the communication flows of the firm at a certain point in time and then diffuse through the organization. Recruiters who are aware of these novel pieces of information, such as the names of potential candidates or news of upcoming layoffs at a source firm, can improve the efficiency with which they match candidates to positions. Receiving more novel information sooner should therefore improve the relative timeliness and quality of these matches and increase project completion rates and revenue generation.

> H3: *Project completion and revenue generation by individuals is correlated with the amount and timeliness of novel information observed by those same individuals.*

Methods
Data
Data for this study come from three sources: (i) accounting data on project co-work relationships, organizational positions, physical locations, projects completed and revenues generated; (ii) email data captured from the firm's corporate email server, and (iii) surveys of demographic characteristics, education, and industry tenure. Email data cover 10 months of complete email history over two equal periods from October 1, 2002 to March 1, 2003 and from October 1, 2003 to March 1, 2004. We wrote and developed capture software specific to this project and took multiple steps to maximize data integrity and levels of participation. New code was tested at Microsoft Research Labs for server load, accuracy and completeness of message capture, and security exposure. To account for differences in user deletion patterns, we set administrative controls to prevent data expunging for 24 hours. The project went through nine months of human subjects review prior to launch and content was masked using cryptographic techniques to preserve individual privacy (Van Alstyne & Zhang 2003). Spam messages were excluded by eliminating external contacts who did not receive at least one message from someone inside the firm.[8] Participants received $100 in exchange for permitting use of their data, resulting in 87% coverage of recruiters eligible to participate and more than 125,000 email messages captured. Details of data collection are described by Aral, Brynjolfsson & Van Alstyne (2006). Since cryptographic techniques were used to protect privacy, we observe unique tokens for every word in the email data and construct diffusion metrics based on the movement of words through the organization in email. Survey questions were generated from a review of relevant literature and interviews with recruiters. Experts in survey methods at the Inter-University Consortium for Political and Social Science Research vetted the survey instrument, which was then pre-tested for comprehension and ease-of-use. Individual participants received $25 for completed surveys and participation exceeded 85%.

Identifying Heterogeneous Information Types
Our goal is to identify event news and discussion topics by their usage characteristics. We defined 'event news' as simple, declarative, factual information that is likely triggered by an external event and of general interest to many people in the firm. Given these criteria, we assume event news is characterized by a spike in activity and a rapid pervasive diffusion to members of the organization, followed by a decline in use. We are also interested in identifying 'discussion topics,' which we define as more complex, specific to a group of people, containing more procedural information and in Von Hippel's (1998) parlance "sticky." We expect this information to exhibit more shallow diffusion, characterized by 'back-and-forth' conversation among smaller groups for more extended periods.[9]

We began with a dataset consisting of approximately 1.5 million words whose frequencies were distributed according to the standard Zipf's Law distribution (see Figure 1). We eliminated words unlikely to represent diffusion words by culling extremely rare words (term frequency < 11), words commonly used every week (appearing in at least one email during every week of the observation period), and words without spikes in activity

---

[8] In this study we focus on email sent to and from members of the firm due the difficulty of estimating accurate social network structures without access to whole network data (see Marsden 1990).

[9] We thank Tim Choe for his tireless coding efforts that extracted and manipulated the email data described in this section.

(low term frequency- cumulative inverse document frequency i.e. "tf-cidf,") a common measure of usage spikes (Gruhl et. al. 2004)).[10] These three methods reduced the sample to 120,000 words.

Table 1: Descriptive Statistics

Variable	Obs.	Mean	SD	Min	Max

Researcher	832419	.22	.41	0	1

In selecting event news, we sought words with a spike in activity and a rapid, pervasive diffusion to members of the organization, followed by a decline in use. We chose words seen by more than 30 people with a coefficient of variation one standard deviation above the mean.[11] To select words likely to display rapid propagation, of words that reached 30 people, we selected words with a coefficient of variation of activity one standard deviation above the mean - words with bursts of activity in some weeks relative to others. The coefficient of variation has been used in previous work to identify spikes in topic frequency in blog posts (Gruhl et. al. 2004) and is a good measure of dispersion across data with heterogeneous mean values (Ancona & Caldwell 1992).[12] Observations of a large number of people suddenly using a word much more frequently than usual are likely to indicate information triggered by some external event that is diffusing through the organization.[13] The result is a sample of 3275 words at first rarely used, then suddenly are used much more frequently and by more than 30 people, followed by a decline in use. We then selected a sample of discussion topic words where users both received and sent the word in email. This simple criterion selected approximately 4100 words from the original candidate set. Examples of the usage characteristics of event news and discussion topics are shown in Figures 3 & 4. Words in this sample display a lack of use, followed by a shallow diffusion to a limited number of people in back and forth discussion, which in the case of the word show in Figure 4 lasts close to 3 months. These words are shared in back and forth conversation as shown in Figure 5. After selecting these words based on their usage characteristics, we tested whether our information types exhibited significantly different usage characteristics and diffusion properties. As Leskovec, Singh & Kleinberg (2006) have noted, information cascades are typically shallow, but are sometimes characterized by large bursts of wide propagation. We wanted to make sure we captured both these phenomena in our data. We therefore summarized the usage characteristics of words along several dimensions including the number of emails containing the word, the number of people who used the word, the coefficient of variation of use, the number of emails per person that contain the word, the total diffusion time divided by the total time in use (as a proxy for use beyond the diffusion to new users), and the maximum number of people who saw the word for the first time in a given day (a proxy for the maximum spike in activity).

---

[10] The tf-cidf constraint chooses words that record a spike in weekly usage greater than three times the previous weekly average, retaining words likely to cascade or diffuse. The cutoff of 11 produced similar results as cutoffs in the neighborhood of 11.

[11] The distribution of employees using common words provides a robust contextual proxy for 'widely used' information in the firm. Using a histogram of common word distribution over the number of people using those words, we determined that most common words were used by between 30 and 70 people (see Figure 2). To be conservative, we selected any word seen by more than 30 people as a potential observation of event news.

[12] The coefficient of variation is the standard deviation of the number of emails per week that contain a word divided by the mean number of emails per week that contain that word.

[13] Event driven spikes in use *not* part of diffusion processes will downward bias our estimates, making them more conservative.

Data Structure

We observe the diffusion of several thousand words of each information type from the first occurrence of a given word in our data, to all employees in our sample. We observe whether a given employee received the word, the rank order in which they received the word, and the time between the first use of the word and the first instance of receipt of the word by each employee. An observation is a word-recipient pair (one for each possible recipient in the firm). We record dyadic characteristics of each first user-recipient pair, such as age and industry tenure differences, for all potential recipients and the individual characteristics of recipients (e.g. gender, network position).

Statistical Specifications

We estimate the impact of hypothesized factors on the likelihood of seeing a information and seeing it sooner. Linear estimates of probabilistic outcomes create bias due to non-linearity at upper and lower bounds of the likelihoods of discrete events. They are not well suited to temporal processes in which outcome variables can be conditioned on previous events and they also produce biased estimates of longitudinal data with right censoring (Strang & Tuma 1993). For these reasons we specify logistic and hazard rate models of diffusion. We first estimate the influence of independent variables on the likelihood of receiving a given piece of information using a standard logistic regression model formalized in equation 1, where parameters describe the impact of a given variable on the likelihood of receiving the word during the ten months of email observation.

$$\ln\left(\frac{P(Y_i = 1)}{1 - P(Y_i = 1)}\right) = \alpha_i + \sum \beta_j X_i + \varepsilon_i \qquad [1].$$

However, pooled cross sectional estimates may wash away temporal variation and allow later events to influence estimates of earlier diffusion (Strang & Tuma 1993). We therefore estimate the rate of receipt of different types of information conditional on having received the information, using a Cox proportional hazard rate model of the speed with which employees receive information:

$$R(t) = r(t)^b e^{\beta X} \qquad [2],$$

where *R(t)* represents the project completion rate, *t* is project time in the risk set, and *r(t)^b* the baseline completion rate. The effects of independent variables are specified in the exponential power, where β is a vector of estimated coefficients and *X* is a vector of independent variables. Coefficients estimate the percent increase or decrease in the rate at which information is seen associated with a one unit increase in the independent variable. Coefficients greater than 1 represent an increase in the rate of information diffusing to the receiver (equal to β - 1); coefficients less than 1 represent a decrease (equal to 1- β).[14]

Finally, we test the performance implications of access to information diffusing through the network. We test the relationship between access to information (D_i) and productivity (P_i), controlling for traditional demographic and human capital factors(HC_{ji}).

$$P_i = \gamma_i + \beta_1 D_i + \sum_j B_j HC_{ji} + \varepsilon_{it} \qquad [3],$$

where productivity (P_i) is measured by projects completed and revenues generated during the period of email observation, and access to information (D_i) is measured by the number of words that were seen by the recruiter, the mean rank order in which they received words relative to their colleagues, the mean time it took for them to receive words, the number of words for which they were in the top 10% and the top 50% of recipients by time, and the number of words they saw in the first week and the first month. Human capital and demographic measures (HC_{ji}) include age, gender, education, industry experience, and organizational position.

Results

Estimation of the Diffusion of Information

We first tested the diffusion of all types of information through the firm (see Table 3). Although employment at the firm is gender balanced and controlling for correlations between gender and organizational position (partner and consultant dummies), men are 55% more likely than women to receive information of all types. Demographic dissimilarity between originator and recipient reduces the likelihood of receiving information by between 1% and 13%, with gender differences recording the largest impact and age differences the smallest. The strength of ties increases the likelihood of receiving information. Ten additional emails sent increases the likelihood of receiving information by 2%. Path length reduces the likelihood of receiving information, with each additional hop reducing the likelihood of diffusion by 29%. Having friends in common seems to reduce the likelihood of receiving an information cascade. However, having friends in common is positively correlated with email volume

---

[14] We found no compelling evidence of duration dependence and proceeded with traditional estimations of the Cox model.

and the strength of ties. Holding these variables constant, the initially positive effects of friends in common reduce and reverse. Betweenness centrality has a strong positive effect on the likelihood of receiving information, as do stronger project co-work relationships.

Table 3. Drivers of Access to Information

Notes: Age, Edu, Industry Tenure not significant. * p < .05; ** p < .01; *** p < .001.

Hazard rate model estimates of the drivers of the rate of information receipt reveal positive effects for project co-work and betweenness centrality, and a negative relationship between path length and the rate at which information is received. These results demonstrate the importance of demographic distance, network structure and project based working relationships on the likelihood of receiving information and the rate at which it is received. We note that network characteristics may be endogenous. Network characteristics may be correlated with information diffusion due to the nature of the selection criteria used to choose words. We therefore interpret parameters estimates of network characteristics as descriptive control variables.

Estimation of the Diffusion of Discussion Topics & Event News

Table 4 presents estimates of the drivers of event news and discussion topic diffusion. Demographic distance reduces the likelihood of receiving both news and discussion topics although with a slightly larger impact for news. One additional year of education difference between two individuals reduces the likelihood that news will defuse between them by 7.5%, while reducing the likelihood of discussion topics diffusing by nearly 17%. Interestingly, men are over 50% more likely to see news than women although gender has no effect on the likelihood of the diffusion of discussion topics. Strong ties are important predictors of the diffusion of discussion topics but not of news. News seems to diffuse pervasively throughout the organization without regard to the strength of ties – information of general interest is passed through relatively weak ties as well. Ten additional emails

exchanged increases the likelihood that discussion topics will diffuse by 7% on average. Path length reduces the likelihood of information diffusion, although the impact is much larger for discussion topics than for news. An additional hop between individuals reduces the likelihood of discussion diffusion by 97%, indicating discussion topics diffuse locally, while news travels across multiple hops. Betweenness centrality increases the likelihood of seeing both news and discussion topics.

Notes: Age, Edu, Industry Tenure not significant. * $p < .05$; ** $p < .01$; *** $p < .001$.

Perhaps most interestingly, strong working relationships and similarity in industry tenure both have strong positive impacts on the likelihood of receiving discussion topics, but not on the diffusion of news. Each additional project that two people work on together increases the likelihood that discussion diffuses between them by 8%. Discussion topics are more likely to diffuse up and down the organizational hierarchy rather than laterally. As researcher is the omitted position category, strong positive estimates on partner and consultant variables demonstrate that discussion is more likely to diffuse upward rather than down the hierarchical structure of the firm. Hazard rate analyses mirror the logistic regression results to a large extent. Men see news at a higher rate than women, although demographic differences do not seem to predict the rate at which individuals see either news or discussion topics. The strength of ties has a strong positive impact on the hazard rate for discussion topics but not for news, while greater path lengths consistently reduce the hazard rate across both types of information. We see increases in the rate at which employees see discussion topics with greater project co-work (6.6% increase per additional project). Having the same area of expertise increases the rate while industry tenure differences have no effect. The partner and consult dummies show that employees in the top two levels of the organization see information at a higher rate.

Access to Information & Productivity

Table 5 presents estimates of the impact of access to information on the productivity of individual recruiters as measured by the number of projects completed. Each measure of access to information captures a

particular dimension of the degree to which recruiters are privy to information diffusing through the email network. 'Words seen' is a count of the number of words each recruiter received in email. 'Mean rank' measures the rank order of receipt for each word relative to other recruiters. 'Mean time' measures the average time in days it takes recruiters to see words. 'Rank 10% (50%)' measures the number of words for which recruiters were in the first 10% (50%) of employees to see the word. 'Words seen in one week (month)' measures how many words the recruiter sees within one week (month). Access to information predicts project output. Each additional ten words seen are associated with an additional 1% of one project completed. Greater mean rank and longer average receipt times are associated with fewer projects completed holding constant traditional demographic and human capital variables.

Table 6 presents relationships between access to information diffusion and revenues generated, a quality adjusted measure of output. These results show economically significant relationships with additional 'word seen' associated with about $70 of additional revenue generated. Strikingly, access to information diffusion is a much stronger predictor of productivity than traditional human capital variables such as education or industry experience.

Conclusion

We demonstrate that demography, organizational structure, and task characteristics all influence the diffusion of information and the likelihood of involvement in information cascades. We also find that different types of information diffuse differently. While demographic distance reduces the likelihood of seeing both types of information, task characteristics such as project co-work and industry tenure differences reduce the likelihood of receiving discussion information more than event news. Discussion topics are more likely to diffuse vertically up

and down the organizational hierarchy, across relationships with a prior working history, and across stronger ties, while news is more likely to diffuse laterally as well as vertically, and without regard to the strength or function of relationships. These differences also strongly correlate with productivity. Information workers who receive more novel information sooner complete projects faster and generate significantly more revenue for the firm. Our findings provide some of the first evidence of the economic significance of information diffusion in networks.
